

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

TO OUR READERS.

— x —

WE were rejoiced to find when in the west of England that this is called "The Rose Journal," and we accept the title as a monitor to endeavour that it shall continue to deserve it. The Rose is our national emblem, and will remind us to watch over the interests of all those to whom we are devoted. To the exiled and to the town invalid as well as to the rubicund country florist let us remember—

"When pain afflicts, or sickness grieves,
A Rose the drooping heart relieves."

Let us endeavour to be welcomed everywhere like the Rose, of which it was said—

"I'll place thee near my soul;
Not in my heart indeed, but in my button-hole."

Let us be welcomed like it at all seasons. "Roses in December" are even more prized than

"When the queen of June
With other flowers abounds, and birds in tune."

Let us be reminded by it to be wisely silent—

"For o'er his desk the editor uphung
The flower of silence, to remind each guest,
When friendly conversation loosed the tongue,
Under the Rose what pass'd must never be express'd."

We will accept the title also as a good omen—as prophetic that our readers and contributors will continue to aid in making this Journal's office a bed of Roses for

THE EDITORS.

INDEX.

ABELIA UNIFLORA FOR WALLS, 504
Abercrombie, John, 469
Aberdeen Canary Show, 21
Abutilon *Boule de Neige*, 310

From observations taken near London during forty-three years, the average day temperature of the week is 41.2°; and its night temperature 39.8°.

COVERING OUTSIDE VINE BORDERS.

MR. ROBSON has handled this subject very ably as regards the production of early Grapes. There can be no doubt that it is bad practice to have the roots of a Vine in a temperature little above freezing when the upper part of the plant is afforded summer heat. Even when Vines have the benefit of a bottom heat of 80° or 90°, as those have which are grown in pots or heated borders, they never commence root-action

till some of the leaves are grown to nearly their full size, and when the roots are in a very low temperature I believe the flowers often expand before there is much root-action. The evils arising from this are patent to every practical man, and I have endeavoured in former papers to show that it is one of the most fertile causes of shanking.

I think, from what Mr. Robson says, he, like myself, would prefer the roots of Vines intended for forcing to be all inside; but sometimes we have no choice in such matters, and when such is the case we cannot do better than follow Mr. Robson's advice. It is, however, principally upon the subject of late Grapes which I wish to say a few words.

I have come to the conclusion that for these also it is the most economical as well as the most satisfactory plan to have the borders entirely inside. I am not now speaking of amateurs' houses where a little of everything is grown, but of vineries proper. I know many who have the charge of extensive vineries will argue that they give their Vines both outside and inside borders, and that they always find the greatest number of healthy roots in the outside border. This only proves that the Vines know their wants better than the man does who has charge of them. Give them what they require in the inside border and they will not then be so likely to ramble outside, as the temperature of the soil under glass is certainly more suitable to them than that of the cold soil outside. In nine cases out of ten I believe it is only a question of water. There are not many inside Vine borders in the country which have a sufficient supply of water. It is of no use measuring the quantity which falls from the clouds in any country and then giving a similar allowance to indoor plants. The conditions are all so different; our borders are so completely drained and so porous, they are generally cut off from the subsoil, and we with all our modern appliances and skill cannot distribute the water so economically as Nature does it. We must always allow for at least three-fourths of the quantity we give running away immediately into the drains, and a much greater proportion even than this at the first spring watering if the borders have been kept dry during winter, as I know many are. It is, however, a great mistake to keep them dry at any time. I do not like watering if it can be avoided when ripe fruit is hanging on the Vines, and I think it is better to have the borders covered with short litter or something else at

such times to check evaporation. Immediately the fruit is off all inside borders require a good heavy watering, and I am pleased to see that the practice of giving them such is becoming every year more popular. The drying of the roots in winter is totally at variance with the teachings of nature, and great injury is committed in ignoring those teachings. The roots of Vines are not, like the Onion and Hyacinth, connected with a bulb to store up matter for future growth, but each root contains its own store, and must be kept moist or its virtues are lost.

If it is argued that there is not sufficient room in many vineries for the roots I say, Consider what is done with Vines in pots year after year, and then reckon up the number of cubic yards of soil a moderate-sized house contains. The fact is, the quantity of soil is generally more than doubly sufficient, but the roots are allowed to dart through the greater portion without making any use of it. It does young Vines much good if they are vigorous to shorten their roots now and then; it gets them into the habit of staying at home.

Mr. Robson says his Hamburgs were not thin-skinned, and he seems to think that they ought to keep better for that. I do not think so. I know Lady Downe's with its thick skin keeps longer than the Black Hamburg, which has a comparative thin skin, but I do not think it is because of the thick skin that it keeps, and I am in hopes of seeing before many years some thin-skinned varieties which will keep. The skin of Alicante with me is not nearly so thick as that of Lady Downe's, and yet it keeps as long as that popular sort does. It is but fair to add that I consider Alicante loses very much in flavour if kept till April, and is not then so good as Lady Downe's. In December and January I prefer Alicante.

Is not a comparatively thin skin on any given kind of fruit a general accompaniment to high finish and other good qualities—not Grapes alone, but Apples, Pears, Oranges, &c.? and do not Grapes which have a comparatively thick skin for their kind, although they colour-up well, generally turn a little foxy-looking afterwards? I have some Hamburgs which have not by any means a thick skin which are keeping very fairly, and I am in hopes of having some of them for the beginning of January. They are grown entirely in an inside border, and were ripe in the beginning of September. I find thick-skinned Grapes, although the flavour may be good, like Mrs. Pince, are not at all popular with the gentry, and I endeavour to make the Hamburgs last as long as possible.

I think we in the southern and western counties have one difficulty with late Grapes which the northern growers do not experience to so great an extent. It is that after the Grapes are ripe in autumn we have such sudden fluctuations of temperature. Perhaps it is frosty at night, and in the morning before daylight we have a temperature of 55° or more. This happened last year very frequently, and at such times, unless a high temperature is maintained in the house, it is exceedingly difficult to prevent moisture condensing on the berries. I therefore

think it advisable not to have the late Grapes ripe in September, as most growers recommend, but that the beginning of October is preferable, because then we can maintain a high temperature all through the month with advantage to the Vines and fruit.—WILLIAM TAYLOR.

A NEW MODE OF GROWING GRAPES.

THIS new mode embraces two alterations of the old mode, consisting in a peculiar construction of building and also in a peculiar construction of the receptacle for the roots. I will not waste many words in the description of my plan.

The house, now seven or eight years old, consists of slanting sides running north and south. These sides are 3½ feet from each other at the top and 7 feet at the bottom, and 9 feet in height; the top is covered with glass in the usual manner. The houses I first built were only 27 feet in length, a door at each end being sufficient for ventilation. The Vines are trained to the sides. The peculiarity of these houses consists in the angle of the sides allowing the rays of the sun to glance off at the time when burning usually takes place. During the several years Grapes have been grown on this plan not a leaf has been scorched, although both doors have been closed for ripening during the hottest part of the day—in fact these houses are sun-traps, the air of which becomes heated to 90° and upwards, the only effect being to ripen and thoroughly blacken the crop.

These houses cost me £12 10s. each; they are imperishable, the wood having been soaked in creosote, and there is no putty. I do not think there has been more than one broken square of glass since their erection; they cost nothing for repairs. Persons from distant parts of the country have come for patterns of these houses. I had not finer bunches or berries of Black Hamburgh in any of the other houses. There is no artificial heat.

My plan of treating the roots of Vines is rather a novel one. Some years since when visiting a vinery at Sootney Castle I observed that there was a trench, 3 feet wide and 3 feet deep, out through the Vine border close to the wall. The gardener informed me he did this in order that he might fill it with leaves, which exhaled sufficient moisture to keep the air from becoming too dry. I have never seen more magnificent Grapes than in that house. He called my attention to the manner in which the roots extended themselves into the leaf mould. He pulled up one of the main roots, the end of which was a mass of rootlets resembling a sponge. I then saw at once the cause of his success; he informed me he cut these off every year, took out the somewhat exhausted leaf mould, and added fresh leaves as before well trodden down. From this description it will be easily seen how the following plan would answer:—

Make a trough 10 feet long by 3 feet wide, and 1 foot in depth, to be slightly slanting to admit of water passing out. This trough can be constructed of wood (the commonest fir being the best) soaked in creosote at 180° temperature. This trough will last for ever if recently creosoted. Pave it on all sides with old turf before planting the Vine. The soil should be of the richest description, and well-rotted leaf mould; there will be 30 cubic feet on five bushels of soil. By the time the Grapes are ripe this will be reduced to about one-half, unless more has been added on the surface, which, if well rotted, has a good effect. When the plant is at rest let four men with four steel forks lift up the entire roots and shake off the soil. If necessary prune the roots, take away all the old soil, half-fill the trough with fresh soil, lay the roots as soon as possible evenly on this surface, and then fill up to the height of the trough, which, if required, may be on small wheels, and if placed inside one of the above houses must be only 7 feet long, and there may be two rods to each Vine. Boards can be placed across the troughs for walking on.—OBSERVER.

IRIS RETICULATA.

THIS charming Iris can be enjoyed only when under glass, but I find that when grown in pots the bulbs become smaller and do not flower the second year. As the price still keeps up I presume that other people are equally unsuccessful. Possibly the plan I adopt with the Persian Iris might answer with this—namely, to grow it in the open border, picking off any flowers. In autumn lift, pot the best plants, and return the others to the ground. Iris pavonia is not hardy enough for this treatment, but it is so cheap that there must be some easy

plan practised in Holland of obtaining bulbs of a flowering size.—G. S.

THE CYCLAMEN,

AND HOW MANY SPECIES ARE THERE IN ORDINARY CULTIVATION?

As the Cyclamen has been recently alluded to, and the names of about a score, either species or varieties, have been mentioned, may I ask how many really distinct species of Cyclamen there are in ordinary cultivation for decorative purposes, and what are their distinctive features? I confess being completely at a loss to make anything like the number put forth as having distinctive botanical names; whereas if every form or change of colouring which a batch of seed will produce has to be dignified with a name the list may be indefinitely extended. If anyone would undertake the task of defining them into anything like a list, however short it may be, of distinct botanical species he would confer a boon on horticulture; or if this be not attainable, would some one give us the leading characteristics of each section?

For my own part I am very sceptical of there being more than three or four really distinct species in ordinary collections, or rather in cultivation for decorative purposes, and very possibly there may not be so many. Where, then, have all the other names sprung from? And how many could with propriety be appended to the very meritorious collections of finely flowered plants that grace horticultural shows in winter as well as in autumn and spring? The difficulty seems the greater from the fact that it often happens that a batch of seedlings from one plant present features widely different from each other both in the making and colouring of the foliage as well as in that of the flowers. The former, which is often regarded as an important part of the plant, is occasionally found with plain rounded leaves devoid of any marking, as well as with foliage of other shapes, and equalling the Begonia in the beauty of its colouring. Now, is it right to call both these examples varieties of *C. persicum*, which seems the most suitable name for the kinds that require the aid of a glass structure in winter, and, in fact, are all the better for a little heat to bring out their flowers at that time? But now and then, in favourable seasons, a fair bloom may be had out of doors in the autumn from the same class of plants when the summer and early autumn have favoured their advancing into flower; but this flowering out of doors, like that of the Camellia under like circumstances, is not always to be depended upon, the ordinary period of flowering being winter and early spring; but that does not answer the question of what species or variety it is related to, or rather to which it belongs.

We all know the ordinary white Cyclamen, that flowers before its foliage very early in the autumn, is a hardy one, blooming with us about the same time as the autumn Crocus, which also presents itself without foliage, and in warm summers both are frequently in bloom by the end of August, the ground often dry and very hard at the time, yet this Cyclamen may often be met with a mass of flowers at that time, nestling at the root of some plant or tree where it is not entirely shaded. But, somehow, it is very shy in producing seed in such a position compared with the tender varieties when planted out in summer. Perhaps, however, the advantages given to the latter in the way of leaf soil and the like in which the plant can bury its seed vessels may conduce to its doing better than one whose seed would seem to ripen in the winter. Be this as it may, I do not recollect meeting with any self-sown plants of the hardy one alluded to, while the other comes up by hundreds in the bed where the plants have been grown in summer.

Now the early autumn-flowering hardy Cyclamen would seem to be quite distinct in every point of view from the greenhouse class, but how many really botanic forms the latter can lay claim to I should like to know; also whether the whole may not be the result of hybridisation, artificial or natural, or both, that has given us the plants now so much admired; and if so, would it not be as well to drop many of the names that now serve no further purpose than swelling-out catalogues of such plants? In doing this I by no means wish to discourage the cultivation of as many varieties as can be had, but I ask, Is it right to give such varieties botanical names? and to ask some one to define what really distinctive species those under ordinary cultivation consist of, and whether giving such names as *C. ibericum*, *africanum*, *neapolitanum*, *persicum*, and others, may not after all be

simply synonyms for one and the same plant found in all these countries, but differing only in a slight degree from each other from causes owing to their sojourn in their respective homes, but which, when exported to others, revert into one and the same form? I wish some one would enlighten us on this head; it would be acceptable information to the general public, while to the ardent cultivator of ornamental varieties it would damp his ardour for improvement to be told his varieties had only one parent. Recent investigation points to more things than *Cyclamens* having only one parent stock. In asking for the information alluded to, I think also that some further remarks on the culture of these plants may possibly turn up during the inquiry.—J. ROSSON.

PARSLEY.

PARSLEY retains the character and uses which it had among the Romans. Pliny says, "Parsley is generally esteemed; sprigs of it are floating in the milk given for refreshment in

Fig. 1.

country places; as a seasoning for sauces it is especially favoured;" and he then commends it as a poultice for weak eyes and tumours. It is needless to particularise the various kitchen uses to which it is now applied, but it may be not so well known that in England it has been worn in the hat "in a braverie," which seems a remnant of the practice of making wreaths of it to crown the victors at some of the Grecian games.

Phillips says that Parsley was not cultivated in England until 1548, the second year of Edward VI.'s reign. This may be so, but we know that it is mentioned as a garden plant in our earliest books, and nurserymen have been specially assiduous to raise handsome curled-leaved varieties for garnishing purposes. The best we have seen is that recently introduced by Messrs. Carter & Co., High Holborn. This is represented in the above woodcuts, but they only approach to the minuteness of the divisions of the leaves. Messrs. Carter & Co. have named it "Fern-leaved Parsley," but "Fimbriated" or "Moss-like" would be a more truth-suggesting name.

LARGE VERSUS SMALL SEED FOR PLANTING.

DR. GUSTAV MAREK has recently published a very valuable monograph on this important subject, embodying the results of a great number of experiments and observations made by

him at the experiment stations at Halle and Leipzig. Most convincing proof of the superior value of large seed is furnished by the results of some of his experiments in the field. Beans and Peas were planted in the garden, small and large seeds of each kind being planted on adjacent plots, the Beans 12 inches apart each way, and the Peas in rows 10 inches apart and 2 inches apart in the row. Not only was the crop carefully harvested and measured when ripe, but the progress of growth was closely watched during the season. The larger and more uniform growth of the plants from the larger seeds, from the beginning to the end of the season, is very plainly exhibited in the condensed tabular form in which we have arranged the results of these experiments. Height is given in inches and weight in ounces, if not otherwise specified.

		Plants from	
		Large Seed.	Small Seed.
BEANS.			
May 28rd.—Height of plants	6-8	8-6	
Average number of leaves	8	6	
June 9th.—Height of plants	12-5	10-11	
June 11th.—Number of plants in bloom	45	12	
June 17th.—All the plants in blossom. Ten average plants taken up from each plot. Average height of plants	34	30	
Average number of leaves on each plant	18	11	
Aggregate weight of the ten plants when dry, in grains	897	576	
July 31st.—Pods fully formed. Whole number of pods	3,186	2,799	
August 5th.—Crop harvested. Total weight of vines and pods	219	186	
Weight of seed, first quality	162	121	
Weight of seed, second quality	6	25	

In whatever way the plants are compared, and however minute the measurements that are made, the advantage remains always with the plants from the large seed. The much greater uniformity of growth cannot be shown in the table without taking too much space, but it appears all through the details given in the original paper. To give one or two instances: Of the ten plants taken up June 11th all but one of those from the large seed had its leaves as given in the table, and the odd one had twelve leaves; on the other hand, of the plants from the small seed some had ten, some eleven, and some twelve leaves, and one had thirteen. The uniformity of the plants from the large seed was marked. At the rate given in the above table the increased yield per acre of seed of the first quality that may be obtained by the use of large seed rather than small would be 250 lbs. A similar course of experiments with Peas gave the following results:—

		Plants from	
		Large Seed.	Small Seed.
PEAS.			
May 28rd.—Height of plants	6-8	4-5	
June 8th.—Height of plants	18	10-12	
June 19th.—Ten average plants taken up from each plot:			
Average height of these plants	44	34	
Average number of leaves	15	13	
Average weight of the ten plants, green	11-5	9	
Ditto, dry	2	1-6	
July 26th.—Crop harvested:			
Total weight of vines and pods	201	192	
Weight of seed, first quality	48-5	19	
Ditto second quality	19	87	

In the case of the Peas as well as of the Beans, the plants from the larger seed are better throughout the season than those from the small seed; the superiority of the former is specially marked in respect to the quality of the seed harvested, as shown in the table.

Prof. Lehmann of Munich carried out a somewhat similar course of experiments with the same plant, and with still more striking results in favour of the use of large and carefully selected seed; and in his experiments not only did the larger seed yield a larger crop from the same number of plants, but a much larger proportion of the small seed failed to germinate in the field, or at least to send the young plants to the surface of the ground, than of the large seed.—(*New York Tribune*.)

THE POTATO.

I REMEMBER it was the late Dr. Lindley who despondently prophesied the decadence of the Potato altogether, and it was this which caused me to first rush into manuscript and to write as follows:—

"Notwithstanding the general failure of the Potato crop this year, what I have privately urged relative to its culture I still maintain. Perseverance in its cause must be insisted on; and in defiance of all that grim foreboders may sing or say against it, I for one intend to plant Potatoes. Let men say all they can possibly say in foretelling its certain destruc-

tion, I answer in reply, We do not live in the times when wiseacres are prophets."

At the present time, according to the "genuine Potato" who "does not like to be under-rated," it is my "novelties" only that are to be extinguished. I am very glad to learn that, because we shall still have some kinds left, and my existence seems to be wound-up in Potatoes of some sort. Certainly the disease came very early this year, and my seedlings being mostly earlyish sorts would be more likely to suffer most this season by consequence; but I could show your correspondent as fine samples of tubers in bulk as even a Scotchman would desire to see. I never had a better yield or one freer from disease, especially Rector of Woodstock, though I scarcely remember the disease to arrive sooner. In nine summers out of ten the *Peronospora infestans* attacks us about the beginning of August, and in nine seasons out of ten the majority of my sorts would be found to be ripe by then and ready to be taken safely from the ground. As to flavour, who shall decide? Why, it was written, to my utter astonishment, by a *confrère* in a contemporary a short time ago, that by some the some of perfection of a Potato should be no flavour at all, but the salt wherewith it was salted! I wonder how the admirers of that dictum would esteem the Dunbar Regent! I certainly have endeavoured to impart a refined flavour into my seedlings, and I was under the impression, along with a host of friends, that I had attained to superior flavour in my sorts. The "DUNBAR REGENT" says No. Well then I will charitably suppose it is uneducated in its taste, and "Sawale" may be enabled to taste more justly than others.—ROBERT FENN, Rector, Woodstock.

GRAPES NOT COLOURING—RIBBED GLASS.

"E. H." on page 482 narrates two instances of Grapes not colouring, the Vines being grown in houses glazed with rough glass. He is at a loss where to attach the blame, and solicits the opinions of others who can communicate their experience.

Heavy cropping alone predisposes to a deficiency of colour in Grapes; in fact, if the Vines are too heavily cropped the Grapes cannot colour well, let the glass or the soil be of whatever nature it may. I think heavy cropping of his Black Hamburg Vines has much to do with the failure of which he complains; this he can conclude if the Trentham Black which coloured well in the same house was less heavily cropped than the Black Hamburg.

But heavy cropping, it should be remembered, is a relative term, and cannot be satisfactorily defined by any given weight of fruit per yard of rod. The condition of the Vines is of primary importance in assessing their fruit-bearing power. A healthy Vine in a good and well-fed border may be lightly cropped with 20 lbs. of Grapes, while another of the same size may be overcropped with half that weight of fruit. We must, therefore, look to the condition of the Vines, and especially the borders, in determining what is a heavy and what a light crop of Grapes. "E. H." is evidently not satisfied with the borders, for he proposes to renew them, and I am, therefore, confirmed in my opinion that the principal cause of the lack of colour in the Grapes is the overcropping of the Vines.

I assume that "E. H." is an amateur, and as the Vines of many are in the same condition as are his I may usefully communicate a little instruction which I think applicable.

The first point to ascertain—Is the border well drained? If it is not I should take the border out; but if it is—if the water can pass away freely (whether by drains or a naturally porous subsoil), I should not take up the Vines and make an entirely new border, as by that operation time, Grapes, and money would be wasted. I should remove the surface soil, baring the principal roots. These I should "notch" at 3-feet intervals by making vertical cuts nearly to the pith, then slanting upward—not downward, mind—to meet them, taking out the pieces. I should then cover the roots with an inch of small charcoal or rough wood ashes, and then 4 or 5 inches of fresh soil. If to this can be added (in the spring, just previous to starting the Vines) fermenting material to raise the surface of the border to 100°—not more—a radical improvement cannot fail to follow. The old roots will emit spongioles, which can be kept near the surface by further dressings of soil, manure, and water. If fermenting material cannot be had, apply in its stead a heavy covering of rich manure, and fresh roots will be certainly but more slowly emitted than by the aid of surface heat. When once a Vine border can be netted with feeding roots to a foot in depth from the surface I care not what is

below; provided the water can pass away, Grapes will be produced above if the management of the Vines is correct. If "E. H." follows this practice and trains thinly, so that every leaf can develop itself, his Vines will improve; but it must be kept in mind that the growths must be disposed more thinly under rough than under clear glass. Every ray of light is important, and every leaf must be free.

I will now state that I do not consider rough glass suited for vineries, and my reasons for so thinking. In my neighbour's garden are a pair of vineries. They are large, and were erected at great cost, and were glazed with rough glass. They have long been in the care of a good gardener, but to colour the Grapes he had to reduce the bunches to less than a "half crop;" to those Vines it was really a full crop. The glass, he was satisfied, was at fault, but the expense of reglazing with clear glass could not be incurred. One day a bright thought struck him that the glass in the vineries, which was rough, and in the frames, which was clear, was of the same size. He measured and found it so, and then with his men set to work and exchanged the glasses, finding sufficient clear glass from the frames to glaze one vinery, the other remaining rough-glazed. The additional light effected a great improvement, much larger crops of Grapes being perfected than in the other division, all the Vines having the same border treatment and temperature.

In hot sunny summers Vines will flourish under rough glass; but in a dull season like the last, and especially where much artificial heat could not be afforded, rough glass is a great obstacle to the production of good and satisfactory crops of Grapes.

With better root-action and in average seasons "E. H." may find his Vines sufficiently improved to prevent him incurring the expense of reglazing; but if expense is not an object he may be tolerably certain that their improvement would be proportionally greater if they could have the advantage of more light—clear glass.—A NORTHERN GARDENER.

NOTES AND GLEANINGS.

WE have had sent to us some specimens of FRISCH'S ORNAMENTAL KALE, various in colour, and desirable for those who use such garnishing.

—A CORRESPONDENT says that a most FRAGRANT ROSE is Baron Haussmann.

—THE prices of admission to the CRYSTAL PALACE are reduced to 1s. on ordinary Saturdays, and 6d. on ordinary Mondays.

THE EUCALYPTUS GLOBULUS AS A PROMOTER OF HEALTH IN MARSHY PLACES.

A few years ago paragraphs went the round of the papers extolling the virtues of the Eucalyptus globulus in rendering marshy places in subtropical and temperate regions more healthy, and, in fact, it was asserted that the plant had the power of expelling fever entirely from such districts. This valuable property seemed almost too good to be credited, although fresh evidence kept forthcoming of its efficacy in that respect—in fact, it seemed that the friends and admirers of this valuable tree were likely to ruin its qualifications by assuming a too extravagant position for them, and the consequence was that for some time afterwards we heard no more of the Eucalyptus and its virtues, and some sceptics went the length of asserting that its qualifications in the way indicated extended no further than the same number of Willows might have done; in other words, that the Eucalyptus was only to be credited for assisting to dry up the marsh on which it was growing, which might be more effectually done by drainage.

This, perhaps, was drawing a conclusion from works at home, without considering the difference which climate, situation, costliness of labour, and several other things intervened to render comparison impossible. It is possible that the Eucalyptus may yet be of service, and it may even deserve all the qualities its greatest admirers attribute to it. Be this, however, as it may—and I do not by any means deny its merits, nor yet admit them to the full—I am pleased again to see it once more brought before the public, and in a manner likely to elicit some useful observations. Without in any way committing myself to any opinion on the case, I strongly recommend it to the consideration of my gardening friends, more

especially to those about emigrating to a warmer country than Great Britain, and any light that can be thrown on the matter will be a boon to the public at large; for the merits of quinine, great and valuable as they are, were not known a few years ago, while at the present time every quarter of the globe admits its valuable qualities. Arguing from that, we have no right to doubt the utility of the Eucalyptus as a health-preserving agent. At the present it is only employed in England as a subtropical decorative plant, where, from its distinct form, and also colour of the stems and foliage, it is very ornamental.—J. R.

OLD TREES.

WELL done, "RADICAL CONSERVATIVE!" what a suggestive letter is that of yours about old trees on page 581. I heartily agree with every word of it, and hasten to contribute my quota upon so congenial a subject, and one, too, of such great importance.

I will at once proceed to offer a few hints on the value of old fruit trees. I have had trees of Green Gage Plum in many forms, from closely pruned dwarf bushes up to tall unpruned standards, and it is a singular fact that I have never had such fine Green Gages as I used to obtain at Egerton off a couple of very old fan-shaped trees trained to an east wall. These trees had spurs projecting quite a foot from the branches, many of which were actually decaying and hollow, and yet most of the fruit was absolutely magnificent, betokening such inherent vigour in the sturdy old trees as enabled them, even in decay, to bear the palm from trees quite free from decay or disease of any kind. I allude to this fact because it taught me never to lay violent hands upon old fruit trees or to adopt hasty or sweeping measures to remodel or improve them. It was a lesson of the greatest value to me, for previously I had been somewhat of an ardent reformer in the treatment of such old trees, regarding crooked limbs and large spurs as monstrosities. Well, there they were together with a grand old Apricot, a Jargonelle, and Beurré Diel Pear, and an immense old Brown Turkey Fig, all with crooked limbs and rugged bark, unkempt and semi-wild; but then they gave good fruit and plenty of it, and when visitors used to exclaim at my droll-looking trees and perchance go away with a somewhat doubtful opinion of their management, I considered myself anything but an object of pity, regarding my bushels of Figs and Apricots and my splendid Gages and Jargonelles as so fair an equivalent for an unsightly tree or two, that I would certainly not exchange them for their trim young trees, and dozen or two of fruit, upon any consideration. These observations may, at first sight, appear somewhat antagonistic to what was said lately about old Peach and Nectarine trees, but in reality they are not so; for while I was content to do no more with the Plum, Pears, Apricot, and Fig than to thin crowded branches and to keep all within bounds, some old Peach trees were cut quite down and made to throw young wood as was stated.

Apricot trees are proverbially tender subjects; canker rides rampant over the majority of them, destroying here a branch, there half a tree, or perchance killing the tree outright, acting in a fitful, capricious, almost mysterious manner. And yet all are not prone to suffer from its insidious attacks. There are notable exceptions in trees both young and old, but the most remarkable are those very old trees like that at Egerton, hale, sturdy, and vigorous, without a blemish, and yielding year by year abundant crops of excellent fruit. Such trees are by no means uncommon, and they are, in my opinion, just so many examples of the good effects of suitable stocks, the result of chance rather than of any wisdom or penetration of those in whose hands the trees originated. I am convinced that a full and sufficient trial has not yet been given to this matter, and that a great deal has yet to be learned on the selection of stocks which are best suited to certain soils. This subject, however, I may approach at a future time.

The treatment of old Apple trees is a matter of too much importance to receive full justice in a paper of this kind, but it may be well to touch a little upon its more salient points. This may be done with some confidence, as I have had several orchards of such trees in my hands at different times. Their characteristics are moss-laden crowded branches—some decaying, others dead, yet as a rule having abundant healthy branches thickly set with bloom buds, the centre of the trees a dense thicket, and with many of the outer branches closely overlapping each other, usually decked with a cloud of lovely pink-tipped blossom in spring, followed in favourable seasons

by an abundant crop of fruit, a large proportion of which is, however, very small.

Now let us take the case of a young man fresh from a first-class establishment where only trees of clean growth and model form were to be found, taking charge of such an orchard of old trees. Well may we inquire, What will he do with it? and that too not without anxiety, for has he not been taught that all crowded growth—aye, and crowded fruit too—is wrong? that in order to keep a fruit tree healthy air and light must circulate freely among its branches? If his training has simply made a routine practitioner of him, working strictly by line and rule, his treatment of the trees is pretty certain to be wrong; but if he be a thoughtful man, and has come to recognise the fact that there are exceptions to all rules, and sees, moreover, that one such is before him, he will proceed with caution and prudence, waiting and watching for a season or two, trying simple measures upon a few trees, and so avoiding any very glaring blunder, for the nature and treatment of old trees is not to be mastered in a season or two.

The results of considerable experience teach me that it is wrong to much thin the growth of old Apple trees; that parasitical lichens are not hurtful to the thick old bark; that there is always an ample play of light and air among their branches to promote health, however dense may be the growth; and that the fruit is quite as useful as that of younger trees, although much of it is small. The mode of treatment which is therefore usually followed is simply to cut away all dead branches, to dust some quicklime upon the smaller branches on a damp winter day, and then to leave them alone. Simple enough, is it not, and very different to the energetic measures which one so frequently meets with? Never shall I forget the dismal aspect of a quaint old rectory garden which I once saw after it had undergone the manipulation of a "new hand." What had been picturesque and tolerably productive old trees were shorn of all their beauty and very much of their utility; hacked and trimmed into conventional form, daubed over with a thick coating of whitewash, there they stood in gaunt unsightliness a miserable example of misguided zeal and faulty practice arising from overweening assurance and thoughtlessness.—EDWARD LUCKHURST.

GROS COLMAN GRAPE.

In your issue of the 23rd ult. you ask for the experience of growers of the above Grape. We have here three Vines of it, all of which have finished-off excellent crops of fruit. The bunches average 4 lbs. weight; the berries are of an immense size, from 4 to 4½ inches in circumference, and as black as sloes. They were quite ripe at the end of September. There are about a dozen bunches still hanging, and the berries are as plump as when first ripe, thus confirming Mr. Tymon's opinion as to its being a late-keeping Grape.

As to quality Mr. Wildsmith's opinion is, that when better known it will prove a formidable rival to Lady Downe's. It requires a strong heat to grow it well, and takes a longer time to colour and ripen than any other Grape I know.—THOS. TURTON, Foreman, The Gardens, Heckfield.

SPENT HOPS FOR MAKING HOTBEDS.—The way I used them was as follows: In any cold pit or frame that might be at liberty I simply placed the hops on the top of any previous hotbed—that is to say, if there was head room enough between the old bed and the glass to add from 19 to 15 inches of hops. They are apt to heat violently if placed too thickly together, and require some watching; but I found them a capital medium for softwooded plants. They are apt to run very close together; and it is a good plan, where there is any old tan which might previously have done duty for hotbeds, to riddle it over and take the small out, the rough to be equally mixed with the hops, and the bed will not heat so violently and will be more lasting than if made of hops alone.—G. R. A.

OUR BORDER FLOWERS—SPIDERWORTS.

We wonder why such strange-sounding terms were given to flowers, names which now are seldom used. The family in hand is only a small one, but if small must not be passed by. The Commelynas are dwarf plants of pleasing habit, with a

profusion of lovely blue flowers. *O. coelestis* is said to be from South America. I fail, however, to see any difference between this species and *O. tuberosa*. *O. hirtella* is a very desirable plant and ought to be more frequently cultivated. *O. erecta* and others might be named also as attractive border plants. In height and colour they are of much the same appearance. *O. coelestis alba* is very distinct, and is an acquisition to all collections of hardy plants. To grow them to perfection they must be well cared for. They should have thorough drainage, or their fleshy roots are liable to perish. They like a sheltered but open sunny situation, and should not suffer for want of water. They require a moderately rich free compost; good sandy

amount of care bestowed upon them. They continue in flower for a long time.—*VERITAS*.

THE FLOWER GARDEN AT HARDWICK HALL.

We append a plan of the flower garden at Hardwick Hall which was described last week. In the design the initials of the Countess of Shrewsbury have the same prominence that is given them on many portions of the old mansion. The plan is engraved on a very small scale, but an idea of the extent of the garden is afforded by the carriage drive which traverses the beds; and the brilliant effect of the large sheets of colour

HOUSE

Fig. 2.—PLAN OF FLOWER GARDEN AT HARDWICK HALL.

loam and peat in equal parts, with a little well-decomposed dung, leaf mould, or decayed vegetable matter, and a sprinkling of sandy grit and charcoal dust well mixed together to the depth of 18 inches, will prove a suitable element for them to develop themselves in.

In some situations the plants will stand through our ordinary winters, but it is advisable to protect the crowns from frost and wet by some dry material, or, what is better, to lift them in autumn and store them in sand, but not too dry, in some cool place free from frost. They should be examined during the winter, as they are liable at times to decay. They are readily increased by seed, which should be sown in spring in gentle heat and the seedlings grown on, hardened off, and planted out in May or June; or they may be increased by division when growth has commenced in spring. They are well adapted for pot culture, and when well grown they are ornamental. As border flowers they cannot fail to repay any

may be appreciated by a reference to the mode of planting which was adopted during the past season.

ROSE-GRAFTING ON ROOTS OF THE BRIAR.

SOME prefer for stocks the Manetti, some the Dog Rose, others the Dog Rose seedling; but I prefer the roots of the Dog Rose or Briar. I am surprised that it has not been mentioned before; it has every advantage over all other modes at this season of increasing stock. The old plan either budded or grafted affords but one plant on one stock, but by grafting on the roots you get many stocks to operate on; for if you go to the wood and lift an old Briar you will find it will give you a good many rootstocks. I lift and cut off the roots and put them into a basket of damp moss. If not convenient to operate immediately I put them in damp soil, and graft on a rainy day under cover.

Any strong-growing Rose root will answer, but the Briar is the best. Now is the time to graft and until the second week in March, but the sooner the better. Most of them will bloom the same season if we like to allow them to do so.

When the Duke of Edinburgh first came to me the first week in February I cut off the top, put it on to the Briar root, and in August I had one of the finest blooms I ever had of that variety.

I have just received most of what I consider the best new varieties, and in a few days their tops will be on the Briar roots grafted in the ordinary way and planted in the open ground, covering the union quite over, and the ground covered with 2 or 3 inches of sawdust. Large roots I wedge-graft, small roots I whip. All the Perpetuals will make roots for themselves, and by this plan we seldom see a Briar sucker.—J. C., Felton Park Gardens.

PAPYRUS ANTIQUORUM.

We figure this example of the Sedges as being typical of an ornamental family of plants, and as being remarkable for the important purposes to which it was employed by the Egyptians. It is not only the plant from which the ancients made their paper, but it gave to paper its name. In Syria the plant was known by the name of *babber*, whence came the appellation Papyrus.

This plant has been employed for various purposes; its leaves by being twisted were converted into ropes, and from its fibre cloth has been made. The rootstocks when young are sweet and nutritious, and are used as food; but when old they become woody, and are then moulded into cups and other utensils. With the rays of its umbels of flowers the Egyptians made chaplets for the heads of their gods, and under the arms of a great many mummies a small bunch of the Papyrus is found; and probably it was of this plant that the "ark of bulrushes" was made in which Pharaoh's daughter found the infant Moses.

In its native habitat it grows in marshy ground to the height of 8 feet, and is surmounted by a large compound umbel of flowers, having long filiform involucres, as represented in the engraving. It is an elegant and stately plant, easily cultivated as a stove aquatic, and is increased from seeds or division of the roots.

More particularly is it useful, perhaps, as a subtropical plant for placing on the margins of ornamental water in the summer months, for which purpose, with other species of the same genus, it is well adapted. When so employed these plants produce a distinct and effective feature in garden ornamentation. A few of the species have been appropriately employed in the streamlets at Battersea Park, where nothing seems to be overlooked.

The Cyperuses, which belong to the same natural order, are miniature forms of this family, growing 2 or 3 feet in height. They are amongst the most elegant of table and decorative plants, of the easiest culture, and all of them will flourish in water or in moist places in the garden during the summer. *C. alternifolius*, the Umbrella Sedge of Madagascar, and its variegated form, are the most familiar and useful, although there are a dozen other species equally easy of culture, *C. longus* being hardy. The tropical species require heat, rich soil, and abundance of water during the summer, and may be safely preserved in a temperature of 50°, or even lower, throughout

the winter; but by growing *C. alternifolius variegatus* in a rich compost it is apt to revert to the normal type. It should therefore be grown in sand. Too much water cannot be given to these plants during the growing season; the pots in fact should stand in water. A supply of plants may be quickly raised from seed, and will do something to fill what is now the greatest blank in garden embellishment—streamlet and water decoration.

THE CULTURE OF THE HOLLYHOCK.

THE Hollyhock is the noblest of all florists' flowers. Towering above all its neighbours like a giant, and in almost every shade of colour, we know no other plant that could take its place. What other could give such a bold appearance to mixed borders? Its flowers will also bear a very favourable comparison with most florist flowers, and stands of its cut blooms form very appropriate companions to the Dahlia, not only on the exhibition table, but almost in all positions. In fact the two are so thoroughly united together in my mind that they almost seem inseparable. As back lines to broad flower borders

they are in my opinion unsurpassed, the noble bearing of the Hollyhock adding to the massive beauty of the Dahlia.

It forms no part of my intention in the following notes to trace the history and gradual yet rapid improvement of the Hollyhock by the skill of the florist. It is quite sufficient for my purpose to know it was introduced from China—a very different-looking plant to what we have it at the present day. It will under certain conditions endure the ordinary winters of Britain—a circumstance I never advise, as I consider it quite worthy the shelter of a cold frame during winter, and that is the only protection it requires except in

sharp weather, when a little extra covering is advisable. It belongs to the order Malvaceæ, which implies that the plant requires plenty of light and water. In giving my method of successfully growing the plant I will first say that it is my usual practice to have at least the half of my stock young plants every year, believing they, in common with many other plants, produce better individual blooms than do old plants; and by having two sets, old and young, the period of flowering is prolonged, the old coming earlier into bloom than the young plants.

For many years after becoming a grower and ardent admirer of the Hollyhock there was no other mode known to me of increasing the stock except by cuttings of the young shoots, and single eyes, before the stems had become hard in the autumn. With cuttings I found considerable annoyance at times through, I believe, my anxiety to push them too quickly with heat. After a time I had pretty fair success with putting the cuttings into a cold place until they were fairly callused; when introducing them into a little bottom heat they emitted roots immediately. Since grafting became known to me, about fourteen or fifteen years ago, I may say I have alone adopted that mode of propagation. I usually graft early in February. The young shoots that spring from the stems are taken off the same as for cuttings. A slice is taken off the side with a clean sharp knife; a corresponding slice is taken off a piece of root, both fitted nicely together, a small pin being thrust through both to keep them from shifting; then blind with mat, pot in nice friable sandy soil, and plunge in smart bottom heat and shade carefully. In eight days or so

Fig. 8.—PAPYRUS ANTIQUORUM

the grafts will be taken and the pots filled with roots, when more light and air must be given, gradually inuring them to the temperature of the cold frame. The plants will now be ready for a shift into 5 and 6-inch pots, and should never be allowed to receive a check till planting out during the first days of April.

We usually plant in lines 3 feet apart; if in open squares, 4 feet between the rows and 8 feet between the plants. In planting always plant the stake first, and then there is no danger of bruising or breaking the roots; and our practice is to leave the empty pot beside the plant, so that we have a covering at hand in case of frost, but never leave the pots over them when not actually required, nor never allow the plants to suffer for want of moisture. They require an abundance of water in dry weather. Syringe also the foliage on the evenings of fine days, both the upper and under side of the foliage, so that red spider may not gain a footing. As the spikes rise tie securely to the stake and pinch out the side shoots. In some instances when the spikes are extra strong I have pinched the side shoots at the second joint and left them for a time. Thin-out the blooms so that they may not be overcrowded on the spike, and when they begin to show colour place something behind the flower to set them out a little from the spike, and top the spikes at 8 or 9 feet from the ground. Early in June I always give them a good heavy top-dressing of rich manure, and if the weather proves dry at the time giving them also a complete soaking of water. With the aid of the mulching they do not become quickly dry again.

The preparation of the soil is a matter of prime importance, as no after-management can compensate for it if defectively performed. In the autumn I manure heavily and trench deeply. After lying as rough as possible to the action of the weather during winter I again trench it over in spring, knocking it well about and breaking it up. I have grown Hollyhocks on the same piece of ground for years, and instead of finding them deteriorate through such a course, on the contrary have found them improve, through no doubt the ground being so thoroughly wrought and deeply cultivated, which I consider of more importance than anything else in cultivating the Hollyhock to the highest degree of excellence.

I append the names of a few out of my collection that I consider worthy of cultivation, believing they are such varieties as anyone may choose from without fear of disappointment. Brilliant, Circle, Hugh Smith, John Gair, John Cockburn, John Stewart, Jane Wilson, James Dalgleish, Lady H. Campbell, Lady Galloway, Lady Eglington, Lady W. W. Wynne, Lord Stanley, Miss Young, Mrs. James Laing, Mrs. B. B. Todd, Octoroon, Pirate, Queen of Yellows, Regent, R. T. McIntosh, R. G. Ross, Ruby Queen, and Sovereign.—J. B. S.

EUPHORBIA JACQUINIÆFLORA AS A WALL PLANT.

For affording brilliant sprays of flowers set in elegant foliage this favourite winter plant is almost unrivalled. Its straggling habit is not favourable to the formation of handsome specimens, yet with the aid of wire pyramids attractive plants may be produced. Small plants more or less compact may also be had by pinching in the early spring months when the plants are in free growth, but the pinching should not be continued after the month of June. Small plants, however, of rather loose habit are often specially suitable for many decorative purposes, as, for instance, affording a graceful fringe, also for intermixing in an informal manner with groups of fine-foliaged plants. Plants of various sizes should therefore always be grown in pots in numbers suited to the decorative requirements of all gardens which afford conveniences for their cultivation.

There is no better mode of growing small decorative plants than by striking the young shoots very early in spring, inserting them in sand and covering with bellglasses, plunging the pots in a bottom heat of 80° to 90°. When rooted they must be potted-off, and be placed in a very light position in the plant stove. The plants flourish remarkably well when plunged in a dung frame, the temperature at night being kept at 60° to 65°. In the summer months the lights may with advantage be removed entirely during warm nights, when the air and dew will promote their sturdy growth—in fact, they may be given the same treatment that is suitable for Poinsettias. At no time should they be overpotted nor suffer for want of water. The soil should consist of lumpy peat and

loam in equal parts, with a free admixture of charcoal and silver sand.

But not more useful are these plants for decorative purposes than for providing brilliant sprays to be cut for various modes of indoor decoration. When grown for this purpose the plants should be planted out and be trained to pillars and vacant walls of stoves, intermediate houses, or early vineries.

Some years ago I had under my charge an early vinery, the back wall of which was entirely covered with this plant. The house was 80 feet long and the wall 18 feet high, and the quantity of sprays cut from that space may be imagined. The Vines were trained thinly up the roof, yet the back wall was still considerably shaded, but the partial shade only lengthened the flowering parts of the shoots. These were not trained closely to the wall, but were allowed to hang in their own natural manner, simply fastening them back to preserve a clear pathway. Very little pruning was given beyond that of continually cutting the flowers and the stopping of an occasional rampant shoot in the summer. The supply of sprays was almost unlimited, and they were much prized. The vinery, it should be noted, was started on December the 1st. During that and the preceding month the Euphorbias looked starved, but by keeping rather dry they received no real injury: they rapidly recovered their freshness with the increasing heat, and afforded out blooms for fully three months.

I have attempted the same mode of culture in late vineries, but have failed in succeeding, the resting period in such houses being too long and too cold for the Euphorbia to endure without injury. In any vineries or Peach houses which are started in January the plant might succeed, as it certainly will do in houses that are kept close from the beginning of December.

The sprays of this plant are so useful and are so generally appreciated that a full supply of them is most desirable, and this can best be afforded by plants which are planted out and grown in the way described. A trial of the plan is recommended in temperate houses where the wall space is not too densely shaded.—AN OLD FLORIST.

A FEW HINTS ON PROPAGATING CONIFERS.

EVERYONE who raises Conifers from either home-grown or imported seeds is well aware of the diversity of colour and habit which the seedling plants assume. This is particularly observable in Lawson's Cypress; but Abies, Wellingtonias, Araucarias, and Piceas show the variation in a scarcely less marked degree; and many of the most beautiful forms of Yew, Abies, Cupressus, and Thuja have been originally either natural variations selected from the seed-bed, or sports perpetuated by grafting the variegated branches on a plant of the green or normal form of the species as a stock. Up to the present time, I believe I am right in saying that we have no hybrid Conifers—that is, no garden hybrids raised by artificial fertilisation; for there can be but little doubt that Conifers, being mostly gregarious and furnished with such ample supplies of easily-wafted pollen, are often cross-fertilised or even hybridised in a state of nature: and another point in favour of this cross-fertilising process having long taken place is, that imported seeds produce such a diversity of offspring. There appears to be no valid reason why we should not raise hybrid Conifers in our gardens now that we have so many fertile or cone-bearing specimens of the rarer and more beautiful kinds; and I strongly urge those who have the opportunity to make experiments in this direction. By crossing the more beautiful and tender kinds with hardier species we might obtain a hardier race, and if additional beauty of leafage or habit, so much the better. Again, some rare Conifers produce ample supplies of pollen before they bear fertile cones, and by using this pollen to fertilise older cone-bearing trees belonging to the same or an allied genus good results might be obtained. No matter, however, whether success or failure is the result, the careful artificial fecundation and cross-fertilisation or hybridisation of Conifers is well worth attention from cultivators, as it appears to be as yet an untrodden path to horticulturists.

The Fir trees belong to a well-known family of graceful-habited Conifers very valuable in ornamental or landscape gardening, and useful as timber trees, and as the source of turpentine in all its forms. This genus (Abies) now includes the Lebanon, Himalayan, and Algerian Cedars (Cedrus). The fully matured cones should be gathered during the winter season, and exposed either to sun heat or to the gentle warmth of an oven or kiln, this treatment being requisite in order to

readily separate the seeds from the cones. The Firs give out their seeds very easily and quickly—much more readily than in the case of the Cluster and Stone Pines, which require the gentle application of heat for several weeks, or even months, ere their seeds can be separated from the close-sealed cones. The method of extracting the seeds from Cedar and other Conifer cones by splitting is tedious, and often injurious to the seeds. M. Delépine of Angers states that the plan he adopts is much simpler and better. About February the cones are buried at a depth of 2 feet underground in sand; they remain thus for a month or two, after which the cones scale easily without force, and the seeds are then picked out and sown immediately, and being swelled they germinate at once. In the case of all Conifer seeds undoubtedly afford the best mode of reproduction whenever they can be obtained; but in the case of rare and new varieties grafting and cuttings have perforce to be resorted to as auxiliary, and in some cases the quicker modes. The cones of Cedars are very resinous when newly gathered, and ought to be left a year before the seeds are separated, much of the resin having during that period passed away by evaporation. The following experiments on the germination of Conifer seeds were made by Mr. J. Alexander, and are recorded in the "Transactions of the Scottish Arboricultural Society:"—"In the year 1870 twenty cones were gathered from each of ten different trees, whose ages were approximately ascertained by counting the concentric circles in other trees felled beside them. The cones were carefully opened, and all the seeds of the ten different sorts sown in separate beds, when the following was the result:—

The seeds of twenty cones from a tree

800 years old	produced 10 plants.	100 years old	produced 106 plants.
250	18	50	104
200	50	15	46
150	74	10	40
125	106		

The same experiment was again tried in 1871 with other trees, when the result was much the same as in 1870.

In a paper on "Gathering the Cones of Resinous Trees," printed in the *Gardener's Chronicle*, 1873, 1557, Mr. Ellison maintains, by illustrative examples, that the premature gathering of the seed tends to weakness in the plants. Foreign seed, he remarks, from the native forests, is invaluable when imported in fresh-gathered cones secured from the trees at the conclusion of the alpine winter, but is not worth having if they have been gathered prematurely. Curiously enough, other seeds have been found to be much improved if left on the plants all winter; and this is notably the case with stock seed.

The latter end of March if mild, or the beginning of April, is the best time to sow all Conifer seeds; and it is an excellent plan to place the seeds in a bag and soak the bag in water for a day or two, taking care to dry the seeds in the sun before sowing. The rarer sorts are generally sown in pots, pans, or boxes of rich earth, and the protection of a pit or frame is given them until they have advanced in growth sufficient to be pricked out in lines in the nursery beds. The more common and hardier kinds are, however, sown at once in nursery or seed beds a yard or 4 feet in width. The richer and more friable the soil the better, and the depth at which the drills should be drawn must be regulated by the size of the seeds, say from half an inch to 1 inch, which, in the case of the larger and stronger kinds, will be amply sufficient. If these seed beds are sheltered by hedges of Yew, Juniper, Privet, or Beech, so much the better. The seedlings may be lifted about a year after they are sown, or in the April following, and pricked out in lines 6 or 8 inches apart, leaving a space of about an inch between each seedling plant; and plants so treated will be found to have made considerably more progress than those left thickly in the seed beds for two years, an old-fashioned plan still largely practised. As a rule seedling Conifers should be lifted every year they are in the seed beds, or until they are either sold or planted out in permanent positions either in the woods or pleasure grounds. If seeds are not obtainable the next best mode of propagating Conifers generally is by cuttings, which should be selected from the side shoots when the sap is in full motion. They should consist of last-year's-growth branchlets, say 4 to 6 inches in length, with a heel of the old wood, which causes them to root better. *Betula nana*, *Taxus*, *Thuja*, *Juniperus*, *Wellingtonia*, *Cedrus*, *Cephalotaxus*, *Cryptomeria*, *Dacrydium*, *Podocarpus*, *Cypripedium*, *Libocedrus*, *Torreya*, and many other well-known Conifers, are readily multiplied by cuttings like those already described. The usual practice is to insert the cuttings or slips in pots,

pans, or boxes of light sandy compost, and place them in a cool and shady frame at the back of a north wall or with a northern aspect. The more tender species and varieties, however, strike quicker and with more certainty if pricked into pots of small crocks, having about an inch of sandy soil at the top. These, if placed in a genial heat of 75° to 80°, will have emitted clusters of white fibrous roots in about a fortnight or three weeks; but they must be carefully hardened off and potted singly, after which they may be placed in a cold frame and finally planted out in the ordinary way. Seed is undoubtedly the best method of propagating all Conifers when it is obtainable, and cuttings are better, as a rule, than grafted specimens, as the latter often throw out lateral leaders instead of terminal or erect ones, and these spoil the symmetry of the specimen. Where the central leaders of Conifers do not start away freely the lateral branches, especially those which grow faster than their neighbours, should be shortened in about October. This throws fresh vigour into the leader and preserves the symmetry of the tree. Many propagators who bud Roses or graft fruit trees with every success finish at operating on Conifers, and this without any apparent reason, except that the plants are a little different in appearance, and this mode of propagation is but rarely resorted to except in trade collections. All Conifers, if not too resinous, may be grafted as easily as a Plum or a Pear. Scions or grafts are selected from the last summer's growth, and are grafted on stocks of the same or nearly allied species all through the winter months in a genial heat, the stocks being seedlings or cuttings grown in small pots for the purpose. Terminal grafting is practised in the spring, taking the scions from the tips of the main branches when in an herbaceous state. The scions may be 1½ to 2 inches in length, and should be inserted on the apex of a seedling or rooted cutting of an allied hardier or less valuable species as a stock. This operation is best performed in a heated close case, or if in the open beds cloches must be used. If in the open air, however, the operation must be deferred until the sap commences to move in the spring. Nearly all the species and varieties of *Picea* and *Pinus* are best propagated from grafts when seeds are not to be had. The Silver Fir, *Abies* (*Picea*) *pectinata*, is an excellent stock for all the finer varieties. The numerous species of *Pinus* grow well on stocks of the different types which they most nearly resemble. For example, those species and varieties which resemble the common Scotch Pine (*Pinus sylvestris*) grow well on that species as a stock, while *P. monticola* or *P. Lambertiana* and their allies do better on *P. excelsa* or on the Weymouth Pine (*P. strobus*). *Cupressus Lawsoniana*, which is readily propagated from seed, and is of clean habit, forms an excellent stock for the dwarf, dense, or variegated form of Lawson's Cypress. Nearly all the *Abies* or Firs take kindly to the common Spruce as a stock, while *Biotas* and *Thujas*, as a rule, succeed well on the Chinese Arbor Vite. In the *Revue Horticole*, 1867, M. Briot states that *Libocedrus tetragona* succeeds as a scion on *Saxifraga*, and its habit, in consequence, becomes changed into a wide-spreading head instead of forming a narrow cylindrical column. *Chamaecyparis obtusa pygmaea* grafted on *C. Bourcierii* grows erect, while if worked on *Biota* or *Thuja*, or if propagated from cuttings, the plants spread horizontally on the ground. *Pseudolarix Kämpferi* is best propagated by grafting scions on its own roots, moderately thick pieces well furnished with fibres giving the best results. This mode might be used with advantage in the case of other rare Conifers which are difficult to propagate by cuttings. Grafting is largely practised in most of the trade collections of Conifers, especially for the multiplication of variegated or distinct varieties of any species. Some cultivators object to grafted specimens of Conifers; but while acknowledging seedlings to be preferable as a rule, one cannot gainsay the evidence afforded by the fine grafted specimens worked by Mr. Fowler at Castle Kennedy, and other well-known cultivators of these fine ornamental plants and trees.—F. W. B. (in *Gardener*).

THE MILE ASH NURSERIES, DERBY.

In horticultural circles the name of Cooling is very familiar and favoured. This applies not to the Cooling of Derby only, but also to the Cooling of Bath. At either town the gardener happening to have a temporary sojourn he would not be likely to omit a visit to their nurseries. I was in the midland town, and without any reference to the alliterative jingle of Cooling and Cucumbers I visited the establishment, and, like any other "customer," I met with

"prompt attention," and once more found what I had often found before, and what "D., Deal," refers to in his happy "Greetings," that the *Journal of Horticulture* ticket is a "sufficient passport in horticultural circles." 18, Irongate, is Mr. Cooling's seed shop, which I found filled to repletion, and undoubtedly doing a "good business," and faced by the

"finest church tower in England"—so say, at least, the loyal people of Derby.

But to the nurseries. These are on an eminence a mile from and overlooking the town. They are exposed to all the winds that blow, and the "stock" is not only exposed to strong winds, but is established in strong soil—clay. A soil

Fig. 4.—Cooling's DERBYSHIRE HEMLOCK CUTTINGS.—(From a Photograph.)

of this nature is shunned by many as being expensive to "work," but it has its advantages, which are here turned to account. In light soil the difficulty is to secure the coveted "balls of earth" to the roots of certain trees and shrubs when being removed; but here the difficulty is the other way. Mr. Cooling, therefore, wisely made it a point in his business to grow largely of ornamental evergreens of a size required for immediate effect, knowing that in this tenacious soil they would remove safely in consequence of the "large balls of earth" that could not fail to adhere to the roots.

These perfected Conifers are a special feature in this nursery;

they are in great demand, and the stock is remarkably fine. Wellingtonias, Cupressuses, Thujas, Piceas, Cedars, &c., are numerous and handsome, the specimens having ample room to develop their forms and preserve their hardihood. In this strong soil also the feathery Retinosporas flourish admirably, as do Rhododendrons, Cephalotaxes, and Cryptomerias.

I mention this because many are deterred from planting these beautiful evergreens in consequence of not having peat or vegetable soil. With care in removal and a little generous soil placed round their roots to start them, nearly all evergreens will flourish in soil of a clayey nature, and in which

they generally assume a healthy hue, and are invariably more hardy than when grown in a lighter compost. Of the commoner shrubs in this soil I need only say that they are as hardy and healthy as such shrubs can be grown.

The Roses are another feature of these nurseries. These are grown in immense numbers, and, as may be imagined from the nature of the soil, in great luxuriance. The theory was once fashionable that Roses of exuberant growth are tender; but practice has disproved the fallacy of that dictum, strong plants raised in strong soil having passed the winters more safely than weaker, and apparently hardier, plants in light soil. Why this should be so has not been satisfactorily demonstrated, yet many have noticed that a gross and seemingly tender shoot has frequently been the only part escaping injury, the smaller and harder-looking portions of the plant being killed; and even if the gross shoot has been injured it has been stricken at its base more often than at its extremity, to the no small surprise of its owner.

Mr. Cooling has a most rich collection of Roses, purchasing every new variety, but increasing only those of merit and in popular demand. They are worked on the Briar and Manetti stocks, the latter being planted more thinly than one often finds them, and the union of the buds with the stocks is proportionally more complete, and the lower buds prominent.

Besides the grounds, which comprise about twelve acres, there are several glass structures devoted to decorative stove and greenhouse plants in the winter and spring, and many of them to Cucumber culture in the summer. Most of these are span-roofed houses, one block containing ten, each 40 feet long by 10 to 15 feet wide. These do not stand separately, but are arranged in triplets, so that three houses have only two external walls, whereas, if isolated, the three would be exposed on six sides. Their union is to economise heat and save fuel. Lead gutters, of course, are formed from roof to roof to conduct away the water.

The plant houses are staged in the centre and round the sides, those which are devoted to Cucumbers in the summer having simply a path down the centre and beds on each side, as shown in the engraving.

It is not necessary to enumerate the contents of each house. The plants generally comprise Palms, Ferns, Jasmines, Bonvardias, Solanums, Ardisias, Pelargoniums, double Primulas (a splendid stock), Lachenalias, a few Orchids, Camellias, and Azaleas very numerous and healthy, and numerous other plants which are adapted for decorative purposes and to meet the great demand for cut flowers, to supply which Pelargonium eckinatum is in great favour for bouquets. Mignonette is also grown in pots extensively and well, and one of the frames contained a splendid stock of *Myosotis asorica*, var. *Empress Elizabeth*. This Mr. Cooling considers one of the most valuable of spring decorative plants, its dense masses of rich blue being strikingly effective. The plants are divided in the spring, and are potted-on and grown much after the manner of Cinerarias. It is one of the indispensable plants in these nurseries, and when in bloom is sold off rapidly.

The Chrysanthemums were fine at the time of my visit, but they are only mentioned to note two useful Pompons, one *L'Escaubouche*, a yellow gem; the other, which is believed to be a sport from *Madame Roussillon*, I will call Cooling's White Button. It is the only variety that is coveted in bouquets, for which purpose it is extensively employed; it is chaste, compact, and pure.

There are other large houses devoted to plants, but on these I cannot profitably dwell; more useful will be a few remarks on the Cucumbers, and especially as the period is approaching when preparations must be made in all gardens for this important crop.

Mr. Cooling is one of the most extensive growers of Cucumber seed in the kingdom. He annually raises large crops of fruit, giving to these crops personal attention, their watering, dressing, &c., being done with his own hands: Cucumber-growing is, in fact, his "hobby" and recreation—a "hobby" the more pleasant by being profitable. The houses are admirably adapted for their purpose, being light, yet having no undue exposure. They are heated by an ample provision of hot-water pipes, which, however, are not seen, the whole being placed beneath the beds, the heat escaping through a series of pigeon holes, as shown in the accompanying illustration. Top and bottom heat is thus afforded by the same pipes, which are placed about 3 feet below the soil to prevent any overheating of the roots.

What strikes the visitor the most forcibly in these houses

are the exceedingly shallow beds or soil-bins in which the plants are grown. In the front next the path these are not more than 4 or 5 inches deep, the soil sloping to the back or boundary wall, where it is about a foot deep. Thus the average depth of soil in the beds is not more than 8 or 9 inches. Mr. Cooling's object is to produce a short-jointed growth, medium-sized stout foliage, and numerous and highly perfected fruits. These requirements he can best attain by shallow soil and very frequent top-dressings; deep rich soil producing larger foliage, longer-jointed stems, and fewer fruits.

The plants are started in small hillocks of pure loam, and a proper (not high) temperature is provided to secure a steady sturdy growth. As their roots protrude through the surface of the soil they are covered with thin layers of fresh soil. When the crop is set richer top-dressings are given, and when the fruit is swelling the plants have copious supplies of liquid manure. To frequent application of fresh soil in, say, 2-inch layers, increasing its richness with the increasing requirements of the plants, and liberal supplies of water, Mr. Cooling attributes his admitted success as a Cucumber grower. Too often do Cucumbers receive just the reverse of this treatment, deep rich soil being given in their early stages, fostering an exuberant growth, and then in their after stages when the crop is crying for support, the only response is an impoverished larder. Only a moment's thought is required to determine which mode of practice is right.

Once, and once only, was Mr. Cooling overtaken with what he regarded as the "Cucumber disease." The crop was swelling to maturity when suddenly the tips of the shoots drooped, the foliage became flaccid, and the stems of the plants ulcerated. Everything that experience could do was done to save the crop, but the disease refused to yield, and the case was regarded as hopeless. As a last resource, however, and applied without hope, an extra application—a strong "kill or cure" dose of Amies' chemical manure was given. The soil was thickly sprinkled and the wounds were thoroughly dressed with it. The effect was magical; the manure acted the part of healer and purifier of the festered stems, and afforded a stimulant to the roots, and the result was that the crop which was given up for lost yielded the best return of seed ever had before or since; the check which the plants received no doubt accelerating the seeding of the fruits. So hopeless was the case, and so complete the restoration, that Mr. Cooling desires that the means he applied may be made known for the benefit of others.

As may be expected not many varieties of Cucumbers are grown here. A few of the best sorts, and these in large quantities and in separate houses, is the system adopted to secure purity of seed.

Judging by the requirements of the trade, *Telegraph* is the most popular Cucumber of the day. *Derbyshire Hero* is also justly popular, and is only superseded, perhaps, by *Tender and True*, and Mr. Cooling's new introduction *King of the Cucumbers*. This is the result of a cross between *Telegraph* and *Long Gun* (the same parentage as the *Osaston Manor Cucumber* now being sent out by Mr. B. S. Williams). The "King" is as productive as *Derbyshire Hero*, light green in colour, of perfect shape, and high quality.

It should be noted in reference to the engraving that the photograph was taken when the fruits were approaching ripeness, and when they are often double their proper table size; also only those were left on the plants which were likely to contain seed, the straight seedless fruit having been cut for use.

In conclusion I may say that not more enjoyable is a visit to these good country nurseries than is an hour's instructive converse with a gentleman of Mr. Cooling's great experience, and his intelligent son and assistant Mr. Edwin Cooling.—J. W.

NOTES ON VILLA AND SUBURBAN GARDENING.

DURING the present open weather an extra effort should be made to complete all digging and trenching in the kitchen garden; but first of all, where the fruit trees are planted by the sides of the walks instead of in regular quarters, the pruning and training necessary should be done; this will leave all neat, and the soil can lay without interruption for some time, which will be an advantage to it; whereas treading the soil in a wet state after being turned up renders it very unkindly, even if it dries up again immediately afterwards.

Plant Garlic and Shallots on a border of good soil, or if only a few are grown they may be planted in a row by the side of the walks, the bulbs being placed 6 inches apart. Make a sowing of early Peas on a border of well-prepared ground. I sowed six early sorts last year, all sown at one time; they were *Kentish*

Invicta, Laxton's No. 1, Emerald Gem, Sutton's Ringleader, Sangster's No. 1, and Laxton's William I. The first-named sort, with Emerald Gem and Sangster's, came into bloom at one time, followed in three or four days by Ringleader and William I. Laxton's No. 1 had not a fair trial, for it was eaten very much by sparrows and pea-fowls, which we have constantly to do battle against here. Invicta and Emerald Gem were ready first, next came Ringleader, and Sangster's a few days later, and William I. and Laxton's No. 1 last. As a summer Pea for good cropping and other qualifications Williams's Emperor of the Marrows is to be recommended; Giant Emerald Marrow also turned out well. G. F. Wilson is a first-rate Pea; and as dwarf summer Peas there are few to equal Veitch's Perfection and Yorkshire Hero (Dixon's), both of which I always grow. I found that Ringleader, Laxton's No. 1, and William I., though not quite so early as the others, were the best croppers; they make more haul and have a more vigorous constitution: therefore those who do not make a point of earliness will not be disappointed by growing either of those last named. I shall grow similar sorts again this year. Beans of the Early Masagan kind should now be planted, if not done before; they will do in a heavier soil than will Peas.

The stock of bedding plants must be seen to now. Amateur gardeners about here are complaining about so many plants damping-off. No doubt their having been placed in common frames during the late snow was the origin of the decay of the plants; but lately there has been ample opportunity to clear them of all dead leaves and otherwise keeping them clean, for if one mildewed leaf is allowed to remain long it is pretty sure to cause the decay of others, especially among the variegated class of Pelargoniums. Fresh air and plenty of it when the glass outdoors approaches 40° is the principal remedy for all damp-affected plants. Old plants of the bedding class that are stored away thickly ought to be looked over and have the dead and dying parts severed from the rest, or they, too, will suffer. If room can be found in the greenhouse the most delicate of them should be taken in. All other store plants, especially Cannas, Dahlias, Marvel of Peru, Fuchsia fulgens, Salvia patens, and such others as have been laid up in earth should be examined, and if any are rotting, which they sometimes do, the decayed part should be cut away, and very dry sand or fine earth should be used to arrest farther injury of the roots. Calceolarias and other half-hardy plants in frames must be treated liberally with air, and in fact, now that all are well rooted, the lights may be thrown quite off all day. Carnations in pots ought to be fully exposed in mild weather, and the frame in which they are placed ought to be hoisted upon bricks so as to admit air beneath the plants.

In the little forcing houses, too, things will begin to move, but for the present—say for another fortnight—the temperature should be kept rather low than otherwise, so as not to excite the buds too much into growth until there is increased light and sun to perfect it. Take care that the house is kept moist enough according to the heat applied, and the plants kept damp overhead. Lillacs, Deutzias, Fuchsias, Hyacinths, Tulips, &c., do not require a strong heat to bring them into bloom, but they require that happy medium of heat and moisture which is so conducive to good health among these plants. By a steady temperature the plants will come into bloom more slowly than under greater heat, but then they will be the better for it and last much longer. Look daily after green fly among Roses and the young foliage of the Strawberries, and for thrips upon Azaleas, and fumigate at once; it is as well to do this once every week as a preventive. Take care that the foliage is dry before applying the smoke, and do not give it too strong, or it will do harm instead of good.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

PRUNING fruit trees, especially standards, pyramids, or bushes, is as much an art that must be perfected by experience as is pruning Rose bushes. The Rose-pruner must know whether his Rose is a weak or a strong grower, whether it is a free or a shy flowering sort, Tea or Hybrid Perpetual, &c. The experienced fruit cultivator prunes for a purpose always, and not by chance. He knows whether the trees are likely to produce a large proportion of young wood, or whether there will be too many fruitful spurs. In the latter case the tree may make such a small proportion of young wood that its constitution might suffer, and it will be necessary to thin out the branches to promote the growth of young wood. Overluxuriant trees must not be pruned closely, and, if not already done, a semicircle should be drawn round the tree according to its size. If the tree is large the radius must be at a considerable distance from the stem. We then dig down to the principal roots and cut them off; then we work under them to the tree, raising all the roots near the surface; the other half of the roots are pruned the following season. This work is best done in November, but it might

be done up to February with advantage. This system of root-pruning is the only certain cure we know for canker if it is done when the tree is first attacked. The branches of standard trees very often become overcrowded from neglect, and those of the bush and pyramid form from injudicious pinching or summer pruning. The fruit produced on such trees is never of good quality, and is always smaller than that produced on trees where the branches have been thinned-out to allow the centre of the tree to be pervious to the light. Our trees have been pruned—at least, what little pruning was required; most of it was done in summer. The ground over the roots has been dressed with rotted manure.

The ground between the rows of Raspberry plants has also been dressed with rich manure, and this will be dug-in at once. Many persons disapprove of digging between the rows, but we have always done so, and our crops are very good. There are certain objections to mulching over the roots of trees and bushes, especially those near the gravel walks, that cannot be disregarded. The mulching always has a literary appearance, and this is the most noticeable at the time when the garden is expected to look at its best—that is, from the end of March onwards; the small birds also are much pleased to scratch the manure, after it has become light from exposure, on to the gravel. Taking these things into consideration it is evident, if we can obtain a crop from trees and bushes almost if not quite as good when the manure has been forked-in as when it is left to litter about on the surface, it is very much better to do so. The pruning of all small fruits has been finished, such as Gooseberries, Currants, &c. All of them receive, like the Raspberries, a good dressing of rich manure. We rather fancy that Gooseberries and Black Currants do better when the ground underneath them has been forked over, plenty of manure being added of course.

We look over the Apples and Pears in the fruit room about once a-week. Both sorts of fruit are keeping very well now. The late Pears have kept better than usual, but the flavour is not nearly so rich as it has been in some previous seasons. We are now using Passe Colmar, Easter Beurré, Josephine de Malines, Winter Nellis, and Chaumontel Pears, the last-named sort from orchard house trees. This is by far the best; except Easter Beurré, which was grown on a south wall, the other three sorts were from pyramid trees. Strange to say the Easter Beurrés are gritty, and in comparison are the worst as regards flavour. The French and Jersey growers are very successful with Easter Beurré from walls. Our experience is that it does not do well on a wall. Many growers, and amongst them the veteran Mr. Thomas Rivers, say it produces the best-flavoured fruit from bush or pyramid trees.

FRUIT AND FORCING HOUSES.

Vineries.—In the early houses where the buds are just breaking we are keeping up a good supply of atmospheric moisture from fermenting material, supplementing this by evaporating troughs over the hot-water pipes, and water sprinkled over the paths and surface of the borders. Red spider seldom appears in houses where a quantity of ammonia is being thrown off daily from stable manure. When the buds are well started and the Vines tied up in their places the borders outside and inside will have a good watering; each time of watering as much is applied as will correspond to a depth of rainfall of 2 inches; we might give more than this, but do not reckon to give less. After the Vines are started no fresh manure should be taken into the house, as the steam from this even in a moderate quantity is injurious. In late vineries the Grapes hanging are Mrs. Pince's Black Muscat, Muscat of Alexandria, Gros Guillaume, Lady Downe's, Royal Vineyard, Waltham Cross, Black Hamburgh, and Snow's Muscat Hamburgh. Of these Lady Downe's keeps the best, but for keeping qualities Gros Guillaume is but little behind it, and is a far more noble-looking fruit. Mrs. Pince has not kept well, and the fruit shrivels much more than any of the other sorts. The keeping qualities of Waltham Cross and Muscat of Alexandria are about equal, both of them keeping better than Royal Vineyard. Of course any decaying berries are removed at once with a pair of sharp-pointed scissors.

Dwarf Kidney Beans.—We do not require to grow these this season, and are truly thankful; they are almost invariably the means of introducing that terrible pest red spider to the houses. Those who intend to grow them should now sow the seed. After trying different modes of treatment the best was thought to be that of planting about six Beans in a 7-inch pot. The compost used was good turfy loam four parts and one part of rotted manure. The pots were not quite half full of mould when the seeds were sown, but as soon as the first true leaves were formed the pots were filled up with soil. If the plants can be kept in a growing temperature and free from spider, and the pods be gathered as soon as they are ready, they will continue to supply gatherings for many weeks. The pots should be placed on a stage or shelf near the glass in a temperature of 60° or 65°, and be daily syringed.

Figs in Pots.—These are usually repotted about the time the leaves fall, but as the operation was omitted at that time it

will be done this week. The Fig is a gross feeder. The compost most suitable for it is good turfy loam, with a fifth part of rotted manure and crushed bones, a good handful of the latter to every peck of the compost. We do not find the trees grow too strongly in pots with such rich compost; if they were planted out it would be different. The compost would then be turfy loam without any manure except what would be applied by surface-dressing after the plants were established.

GREENHOUSE AND CONSERVATORY.

The Camellias are now furnishing us with a few flowers. Last year the same plants were not in flower until the end of February, but as soon as the flowering period was over the plants were placed in ainery where the night temperature was from 65° to 70°. They were freely syringed twice a-day, keeping a moist atmosphere. The result was a splendid growth, with large healthy foliage and plenty of flower buds. We have discontinued turning the plants out of doors after the buds are set. They are removed from the vinery to the greenhouse, the latter being kept rather closer if the weather is cold, but it is not usually so at that time. There is great variety of colour and formation of flowers amongst Camellias, but the very old sorts are not quite eclipsed by the recent candidates for popular favour. The old Double White and Fimbriata are still the best whites, and Imbricata is still one of the best red sorts; they are also profuse bloomers.

Cinerarias now require attention. If the pots are filled with roots, and the growth of the plants is not too vigorous, every alternate watering should be with weak liquid manure. The plants intended to flower in March and April, if handsome specimens are intended, must now have the flowering growths tied down, as the more dwarf the plants can be grown the better. A good plan is to fasten a wire or a piece of stout rope yarn under the rim of the pot, and with the aid of a few sticks inserted in the pot the flowering growths can be tied into their places. Tying and training *Dentata gracilis*. This is a plant that should be grown in every garden. The plant is quite hardy, but to be quite successful with it it must be treated as a greenhouse plant, except that it can be wintered in a house without artificial heat. Some cuttings and suckers from the roots have also been potted. The pots are placed in a cool frame at present, in a week or two they will have the advantage of a little bottom heat. Small bushy little plants in 4 or 5-inch pots, covered with their snow-white flowers, are objects of extreme beauty. The cuttings and suckers put in now will, with good management, form nice plants next season. *Fuchsias* have been placed in a little heat, and when the growths have started a few inches, cuttings of them will be put in. Early-struck cuttings of this graceful old plant are very useful for making a display in the greenhouse in the months of July, August, and September. With *Fuchsias* and a supply of the best sorts of zonal *Pelargoniums* there will be no lack of flowers for those months.—J. DOUGLAS.

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

WESTMINSTER AQUARIUM. April 12th and 18th, May 10th and 11th, May 20th and 21st, July 5th and 6th, October 4th and 5th.

MAIDSTONE (ROSES). June 21st. Mr. Hubert Bensted, Rockstow, Maidstone, Sec.

SPALDING. June 21st. Mr. G. Kingston, Sec.

SOUTHERY. July 6th, 7th, and 8th. Mr. E. Martin, Sec.

HELMSTON (ROSES). July 12th and 18th. Mr. J. Mitchell, Sec.

DUNDRE (INTERNATIONAL). September 7th, 8th, and 9th. Mr. W. E. McKelvie, 25, Euclid Crescent, Sec.

TRADE CATALOGUES RECEIVED.

Waite, Burnell, Huggins, & Co., 79, Southwark Street, London, S.E.—*Wholesale Price Current of Seeds, &c.*

J. C. Wheeler & Sons, Gloucester and London.—*"Little Book" of Seeds. Illustrated.*

J. & F. Howard, Britannia Iron Works, Bedford.—*Illustrated Catalogue of Implements.*

Robertson & Galloway, 157, Ingram Street, Glasgow.—*Descriptive Seed Catalogue and Amateurs' Guide.*

Hooper & Co., Covent Garden, London.—*Gardening Guide and General Catalogue.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee sub-

jects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOK (Bacup).—The work containing woodcuts of plants generally is Loudon's "Encyclopedia of Plants." We cannot read the name of the plant that sheds its leaves.

TENANT REMOVING A GREENHOUSE (Nurseryman).—It is always preferable to obtain the landlord's written permission to remove any greenhouse or other building you wish to erect. If he refuses to give such permission it is easy so to erect them that you can remove them without his leave. If the foundation is of brick, have a plate of wood fixed to it, and to that plate have the superstructure attached by screws. The whole superstructure may be then removed. The boiler, pipes, &c., may be removed also.

EVERGREENS UNDER TREES (S.).—There is often great difficulty in getting shrubs to grow in the shade of large deciduous trees from the ground being occupied with their roots, and which speedily spread into the loosened soil made by planting the shrubs, making the soil too dry for the safe establishment of the evergreens. *Laurustinus* and *Rhododendrons* do well under trees, also *Aucubas* and *Hollies*. Common Laurels and Yews are good, as is also *Evergreen Privet*, *Portugal Laurel* growing for the most part weak and leggy. We should face next the turf with *Berberis Darwini*, then *Laurustinus*, as they will bear any amount of cutting-back which may be required, backing the *Berberis* and *Laurustinus* with *Rhododendrons*, completing with common Laurel, *Evergreen Privet*, Holly, and Yew. Promiscuous planting is for such places far preferable to any formal arrangement of the shrubs, and mixed planting we should adhere to except for the front lines, and in these uniformity in height and outline is often desirable.

BERRIES ON BUTCHERS' BROOM (Idem).—We do not know of any method to promote them other than by fertilising the flowers, or gently shaking the bushes, which would cause the distribution of the pollen. The plants will shortly be in a fit state for operating upon.

DESTROYING GRUBS (A. T.).—Gas lime is good against most descriptions of grubs that prey upon the roots of vegetable crops. It may be applied now or in March prior to planting or sowing, spreading it evenly over the surface, and at the rate of twenty bushels per acre, and point-in with a fork. For your quarter acre you will require five bushels, and the ground being vacant apply now. Gas lime is preferable to ordinary lime to use against grubs, but that is also good, and that you may apply if there be an objection to the gas lime during March, at the rate of twenty to thirty bushels per quarter acre. The greater quantity is not too much.

WINTERING COLEUSES (H. B.).—They winter best when under rather than overpotted, and kept moderately moist in a night temperature of about 55°, and 80° to 66° by day. We should defer repotting them, unless the plants are in very small pots, until February. They do well in turfy loam with a third of leaf soil added.

RAINING MUSK FROM SEED (Idem).—Sow the seed in February in gentle heat, and again early in March, keeping near the glass, the soil being kept moist, and a moist atmosphere maintained.

APRICOT TREES DROAVING (A Constant Reader).—The most likely cause is the high and bleak exposure to which the trees are subjected. A coping board would be a great assistance when the fruit is ripening, also for protecting the young tender fruit in spring and early summer. You will not, we fear, find the trees covered with glass as you propose answer so well as Peach trees, though they would afford earlier and better-ripened fruit under glass than against an unprotected wall. It would have suited better to have had the Peach trees against the wall in place of the Apricot trees, with a clear space of 4 feet from the wall, so as to admit light to the base of the trees. Nothing is gained by crowding, and we advise the Peach trees you have in front to be thin rather than crowded, and with two rows of trees you will in a few years have trees that will crowd each other or encroach upon the trees on the wall, which, as before stated, must have light, and the other trees also, or they will become bare at their bases, unsightly, and unproductive.

BOUGAIVILLEA SPECIOSA NOT FLOWERING (Idem).—It usually grows very freely, but does not flower at all freely. Water copiously up to August, and after the beginning of that month keep dry, not giving any water unless the foliage flags, and then only enough to recover its freshness, affording unobstructed light. It may probably show for bloom in winter or spring, when, of course, free watering should be resumed. Prune as little as possible, which only tends to growth, merely thinning the shoots to prevent overcrowding.

MULCHING PEAR TREES (Henry F. F.).—You may now apply the mould soaked with urine as a mulch or top-dressing to the Pear trees as far as the roots extend, but we should not put on a greater thickness than an inch. This is not the best time to apply guano, but you may apply the fowls' dung to the flower and vegetable garden now, applying to the surface, and rather thinly, as it is a powerful manure, and point-in with a fork. Fowls' dung being like guano, rich in ammonia, is highly stimulating, but is soon exhausted, hence neither should be used any length of time previous to the putting-in of the crops, its value as a manure being thereby greatly diminished, especially in light soil. Liquid manure made of guano kept in a tank will be constantly giving off ammonia, and ought so soon as it is dissolved to be applied to the purpose it is intended for; but we cannot say how long it would retain its value as a fertiliser in a liquid state, but would be more or less subject to daily loss from evaporation.

GOOSEBERRY BUSHES DISEASED (T. W.).—There is no disease on the sprigs sent that can be cured by dressing the bushes with any mixture. The soil is either poor or undrained. The Gooseberry bush delights in deep moderately rich soil.

PEACH TREES ON BACK WALL OF VINERY (W. K. F.).—We do not advise you to plant trees in the position you name. Peach trees do not succeed well under Vines at any season; but starting the house in November it would be proportionally difficult to manage the Peaches successfully.

PEAS FOR SUCCESSION (Nemo).—For a large supply of inexpensive kinds, growing about 8 feet high, we recommend Dillstone's Early, Princess Royal, Velch's Perfection, and Hair's Dwarf Mammoth. Late Peas are all comparatively dear, but a given quantity of seed will sow a greater length than the same quantity of early Peas. Thus, if a pint of early Peas will sow a row 60 feet, a pint of late Peas will sow one 80 feet in length. Sow a large breadth of Dillstone's now, and when these appear above ground sow a similar breadth of the same sort, and also on the same day a like breadth of

Princess Royal. Follow with Princess Royal at suitable intervals throughout March and April, making two sowings of Veitch's Perfection in May. During the first week in June make a sowing of twice your usual size of Hair's Dwarf Mammoth, and with good cultivation and a favourable season you will have Peas of good quality until the middle of November. We have frequently, for the sake of economy in both seed and labour, obtained a large supply of good Peas by sowing Auvergne in drills 2 feet apart, letting them grow without sticks or any other support. This is a most useful sort for a dry district.

PRIMULA JAPONICA LONING FOLIAGE (E. M. S.).—It is usual for these plants to lose most of the older leaves, the plants becoming almost, and in some instances quite, deciduous. We had plants in a similar state to yours some time ago, which are now in a greenhouse throwing up strongly for bloom, which we have no doubt yours will do in a short time, the soil being kept moist, but avoid overwatering, increasing the supply with the growth. From the description you give of the insects infesting the Geranium we think you were quite correct in concluding they were red spider.

HYACINTHS IN GLASSES (Mrs. W.).—We cannot say "why some Hyacinths in glasses throw out small offsets and not others," only that they exist in embryo at the side of the bulbs when introduced to the glasses in the case of those now having them. Usually those having offsets are loose and light as compared with those having the bulbs firm and heavy, which last give the finest spikes. It does not injure the bulbs to break off the offsets, and this ought to be done, as they appropriate the support that would otherwise be expended upon the foliage and spike from the bulb.

MANURING ROSES (Midland Counties).—The winter dressing of manure ought to be given now, though we prefer to give it early in December, quite as much as a means of protection against severe weather as a manuring agent. The best application as a summer dressing would be cool manure, as that of cow dung, applying it when the flower buds appear, watering very liberally after the blooms show colour twice a week, and afford liquid manure once a week between the other waterings. A good preparation for your soil would be a peck each of fresh cow dung and soot in fifty gallons of water; falling that, 1 lb. of guano to twenty gallons of water. If the weather be wet the watering will not, of course, be necessary, but the liquid manure should not in that case be omitted. About the middle of July apply another top-dressing of manure, watering copiously in dry weather, and the liquid manure as before, which will give you fine late summer blooms. Mulching is very good, preventing, as it does, evaporation, and securing greater regularity of moisture. Grass mowings as a mulch are likely to be of benefit, but we should only use them thinly over the top-dressings of manure.

PRUNING ROSES ON THE MARITIME (G. Y.).—We should prune the first mild weather after the middle of February, or at that time if severe weather is not prevalent. The shoots 6-feet in length we should cut back to six eyes of their base, and those of 3 feet to four eyes, and if the wood be weak to three or two eyes, according to its vigour. Those with the lowest branches 2 feet from the ground must have been neglected in the previous prunings. We should seek to originate shoots nearer the surface by cutting a fair proportion of shoots of the length you state to within 6 or 8 inches of the soil, and securing shoots from those, serve the remainder the same way at the succeeding winter pruning, and having them once well furnished at the base, endeavour to keep them so, as nothing is more unsightly than a leggy Rose bush.

INGRAM'S PROLIFIC MUSCAT VINE.—Dr. Pearson, Kensington, wishes to know where he can obtain plants of this Vine raised from eyes. Oyster shells can be calcined in any fireplace or furnace. We do not know where they are to be bought calcined.

ASPIDIUM TRICHOMANES (G. McDougall).—The varieties you send we think will not be permanent, and differ but little from the normal form. We never heard of a variety called "majus."

POTATO FOR LATE USE (B. Bradford).—Plant either the Finks or Lapstone Kidney.

NAMES OF FRUITS (E. Brewster).—We have repeatedly requested that only six specimens be sent for identification. It requires more time than we can spare to find the names of many. There are thousands of named Apples and Pears. One gentleman sent us two hundred specimens, and asked that they might be named "in the next number." (E. B., Dublin).—1, Gilgill; 2, Doyenné d'Été. (E. V. R.).—Golden Russet. (J. Collis).—You have not numbered them. The round one is Gloria Mundi, and the conical one Beauty of Kent.

POULTRY, BEE, AND PIGEON CHRONICLE.

PRIZE CARDS.

THERE seems to be quite a commotion about prize cards at the present day. Exhibitions appear to compete with each other in producing new cards, highly coloured and elaborate. We have always noticed that the amateur in the commencement of his winnings is anxious to obtain these first trophies of his success, and even older fanciers much delight in collecting the pieces of pasteboard from the various meetings wherewithal to paper their poultry rooms or nail up over their pens. We have seen rooms of good dimensions profusely covered with these cup and prize cards, and a very pretty effect they made; but good-bye to such vanities in future if we have to pay for them, as would seem now to be becoming the fashion. When the fee is paid and the cost of carriage is deducted we generally find but a meagre remainder to put on the credit side in the case of an ordinary prize; but then to have something else deducted for a card is positively too much to submit to, and yet such is the case. We can all remember the outburst of indignation when, many months ago, the authorities of the Bromley Show thought well to charge 1s. for an embossed card. We came among the recipients of these souvenirs, and though we would sooner have had the shilling, yet we are bound to say that they were better worth a shilling than the pieces of card we have lately had to pay for. Within the past week we have had sums deducted from our prize money at two shows, the one being 1s., the other 4d. The latter was for an ordinary card with an im-

pression of a Coochin hen printed in bronze from a cut, we should say, of the defunct "Poultry Review." The shilling article, however, although deducted from the prize money some days ago, has not yet come to hand, but we are looking forward to its arrival with great interest. In the interval, however, we write most strongly against the system, and beg other exhibitors to help us in crushing any plan so ridiculous as that of paying for our prize cards.

We do not for a moment wish to advocate the plan lately adopted by an eastern county of putting no prize cards on the pens at all, so that they may be clean to go by post. That is as unfair as it is absurd, for the spectators who pay to come in to see the prize pens should at once be able to detect them without having to invest another sixpence or a shilling in the shape of a catalogue, which is to many, especially to the evening frequenters of poultry shows, as so much Hebrew. The cards, too, should be put up as soon as possible after each class is judged, and be plainly and clearly printed. They should also be of no colour where injurious preparations are used to obtain the same, as many of the birds for amusement eat these cards, and consequently suffer. In fact we all remember, a year or two back, Mr. Brooke losing a splendid Malay pullet from devouring her green prize card. But if a society thinks well to send clean cards round afterwards gratis well and good, for it gives an immense amount of pleasure to beginners in the fancy to store up these cards. Oxford did this, and we believe Edenbridge did also. Anyhow, we know Oxford did, and sent, too, infinitely better and prettier cards, most of them, than we had to pay for the other day.

As, however, the number of exhibitions where these extra cards are afterwards sent round free is but limited—and naturally so, for beyond the cost of printing there is likewise the postage; but as, however, the number of amateurs and others who rejoice in getting their cards back clean is great, we wonder the plan of a card-pocket in the baskets is not more resorted to. We know some do have these pockets in their baskets, but the number is so few that the packers at shows find it hardly worth the trouble to look for them. We read the other day in a letter from Mr. Nicholls, one of the Alexandra Palace Secretaries, that this was frequently the case, and we can quite understand it. If, then, exhibitors put enough stress upon these cards as to care to have them whole and clean, let them put these pockets for the purpose at the sides of their baskets, and the poultry-show attendants will soon learn to look for and make use of them. But this must become a general practice, and the pockets must be placed where they can easily be found, for a packer at a large show, where he has a great number of pens allotted to him to pack, has no time to hunt through the lining of a basket for a card-pocket, and so often, too, after all unsuccessfully; whereas if he was to know it is most likely to be there, and it is placed in a prominent place, we should have no more of those ridiculous letters clamouring for clean prize cards.

Then a word as to the get-up of these cards. We do not think they can be too plain. Fair-sized white cards with the honours clearly printed on them in red, blue, brown, or black should answer all purposes, for these are quickly read by the spectators, and after all that is what they are for. We have seen lately really extremely pretty cards in use, with almost a miniature landscape printed upon them, but we think they fail in not being sufficiently able at one glance to show what honours they record; for though all the first prizes may be in one colour, and all the seconds in another, and so on, still they do not answer the purpose so well as a clean card with the prizes printed upon them in large characters which can be understood in a moment.—W.

CANTERBURY POULTRY SHOW.

As one of the managing Committee of the late Canterbury Poultry Show I beg most emphatically to deny that sawdust was used in the pens of the birds there. For fear of any inaccuracy on my part I have communicated with the Secretary, and he has assured me none was used for such a purpose. Silver sand was used for the pens, and that only because, being snowed up, the oorn-dealers had not straw enough by them to cut into chaff, which has always been used by us on previous occasions. Sawdust was used for the floor, and for that only. Had it been used in the pens I, as a member of the Committee as well as an exhibitor, should have been one of the first to object.—WILLIAM SAVILE.

RIPON SHOW OF POULTRY, &c.

THE Committee was almost entirely formed of hearty fanciers, and with enthusiastic Mr. Wells at its head. The number of entries was more than could be well disposed to light. With true Christmas consistency the ponderous breeds were at the head of the list, *Geese*, *Turkeys*, and *Ducks* taking the lead with a grand display, but unfortunately in rather a dark part of the building. *Brahmas* came next, and among these were some good birds; the *Dorkings*, *Spaniards*, and *Cochins* also very good

classes. *Hamburghs* were very excellent as a section, as also the *Game*, of which there were three classes. Among *Game Bantams* we noticed some good specimens, but many were but poor; and some of the *Black Bantams* were good in all points, but somewhat large. *Polish* were a grand class; but we did not consider the *French* varieties equal to them. There were two Selling classes, and many of the birds were very good.

The *Pigeons* were a nice display; the point cup was carried off by Mr. Horner, also a good number of substantial prizes. In Carriers the first was a well-developed Dun cock; and second a Black, and which was readily claimed at £6, a very low price for such a bird. Pouters were first grand Black, second Blue, and third Yellow. Barbs a large class; winners good, as also pen 334 (Mawson), but some were very plain. In Almonds first was a grand hen; the second a cock of very good head properties. Any other Tumblers, first a splendid Red, second a Kite, also good. Owls were first foreign White, and second a Blue English. In Turbits many were dirty, but the awards were evidently made to head properties alone. Nuns and Jacobins good, but many said to be trimmed; but the winners were evidently honestly shown. In Antwerps the winners were Short-faced Silvers. In Dragons first was Blue, and second Yellow; and in the Variety class the first was a Blondinette, and second Red Swallows, both grand birds. In the Selling class were some Carriers well worth the prices, and these were the winners of first positions.

For *Rabbits* there were but two classes—viz., one for Lops, and the other for any other variety; and in the first a Sooty Fawn, 22½ by 4½ was first; and second a Blue doe, 21½ by 4½, several others being almost equal. In the next class first was a very promising Silver-Gray, second a Patagonian, and very highly commended also a Silver.

TURKEYS.—1 and special, Mrs. Kirk, Ripon. 2, G. Mangles, Ripon. *Ac*, I. Moorey, T. H. Foden.

GRAYS.—1, J. W. Netherland. 2, I. Moorey, Ripon. *Ac*, J. Nicholson, T. P. Carver, G. Mangles, R. Garbutt, T. Mason, C. Hubbard.

DUCKS.—*Aylesbury*.—1 and 2, C. Holt. *Ac*, Col. Cathcart, Mrs. R. Williamson, J. Brookwell. *Rouen*.—1 and special, J. White. 2, J. Newton, Sliden, Leeds. *Ac*, I. Moorey, C. Graham, C. Holt. *Ac*, J. Brigham, G. Mangles, E. Jackson, Mrs. J. Greaves. *Any other variety*.—1, G. Saddle, Boroughbridge. 2, Col. Cathcart, Kirkby Malzeard.

BRAMBLER.—1 and special, E. Ryder, Hyde. 2, J. Holmes, Chesterfield. *Ac*, Williams & Sons, Miss Cotes. *Ac*, J. Holmes, G. Mangles, H. Wilkinson, J. F. Smith.

DORKINGS.—1 and *Ac*, J. White, Northallerton. 2, J. Newall, Clifton.

COCHIN-CHINAS.—1 and special, G. H. Procter, Durham. 2, C. Turner, Stockton-on-Tees. *Ac*, S. Watts. *Ac*, Simpson & Dodds, C. Carr, Williams & Sons.

FRANKS.—1, H. Beldon, Giltstock, Bingley. 2, J. Powell, Bradford. 3, J. Thresh, Bradford. *Ac*, B. Dale.

HAMBURGH.—*Golden-pencilled*.—1, H. Beldon. 2, Holmes & Destner, Great Driffield. *Ac*, J. Preston, H. Beldon. *Silver-pencilled*.—1, 2, and special, H. Pickles, Early, Leeds. *Ac*, Holmes & Destner, G. Alderson, J. Preston.

HAMBURGH.—*Golden-pencilled*.—1, T. & G. Kidson, Thirsk. 2, J. Preston, Bradford. *Ac*, H. Pickles, H. Beldon. *Silver-pencilled*.—1 and special, H. Beldon. 2, H. Pickles. *Ac*, B. Myers, H. Pickles.

GAME.—*Duckwing or Broken Red*.—1 and special, W. & H. Adams, Beverley. 2, W. Milner, Bradford. *Ac*, J. Newall. *Ac*, Holmes & Destner, J. Braithwaite, W. Youngusband, W. Johnson, W. Ormerod, W. Clough, J. Robson. *Any other variety*.—1, W. Milner. 2, H. C. & W. J. Mason (Pile), Birstall. *Ac*, J. Cowper, Holmes & Destner (Pile), W. Johnson, R. J. Smith (Black Red). *Any variety*.—*Cock*.—1, W. Johnson, Guiseley. 2, R. Payne, Bramley. 3, W. Milner. *Ac*, L. Sherwin, G. Carter, W. & H. Adams.

GAME BANTAMS.—*Black Red or Pile*.—1 and special, J. Braithwaite, Bedale. 2, G. Carter, Bedale. *Ac*, E. Holt, Williams & Son, A. Sanger. *Any other variety*.—1, W. Hudson, Epworth. 2, Williams & Son (Brown Red), Ripon. *Ac*, Simpson and Dodds (Duckwing), Bedale.

BANTAMS.—*Black or White, clean-legged*.—1, C. & J. Illingworth, Hightown, Northampton. 2, J. Preston. 3, H. Beldon. *Ac*, Holmes & Destner, C. J. Young, G. Raper, W. Jackson, R. H. Ashton. *Any other variety*.—1, T. P. Carver, Boroughbridge. 2, W. Richardson (Gold-ledge), York. *Ac*, T. Adley (Japanese).

FULARDS.—1, H. Beldon. 2, A. & W. H. Silvester, Birmingham.

FRENCH.—1, W. Jackson, Lancaster. 2, J. G. Knight, Ripley. *Ac*, J. G. Knight, B. Milla, T. S. Tate.

ANY OTHER VARIETY.—1, H. Beldon. 2, H. Pickles (Black Hamburgs). 3, W. Riley, Bingley. *Ac*, Benson & Milner (Black Hamburgs), W. Linton (White Leghorns), J. Preston, H. Pickles (Black Hamburgs), Holloworth & Horner (Sultans, Black Hamburgs, Japanese), J. Newall (Black Hamburgs).

SELLING CLASS.—*Cock or Drake*.—1, T. P. Carver. 2, J. Powell (Spanish). *Ac*, T. & G. Kidson (Golden-pencilled Hamburgs), Simpson & Dodds, G. Milner (Rouens), C. Holt, J. Roberts (Rouens), G. Carter, H. Beldon, Burch and Boulter. *Hen or Duck*.—1, W. Clough (Dorkings), Skipton, Leeds. 2, H. Wilkinson (Brahmas), Skipton, Leeds. *Ac*, J. Johnson (Light Brahmas). *Ac*, T. and G. Kidson (Golden-pencilled Hamburgs), G. Mangles (Rouens, Brahmas), C. Holt, R. Glasby.

PIGEONS.

CARRIERS.—*Cock or Hen*.—1, E. Horner, Harwood, Leeds. 2, E. Beckwith, Sunderland. *Ac*, E. Mawson, W. Hughes.

POUTERS.—*Cock or Hen*.—1 and 2, J. Hainsine, Hull. 2, R. H. Blacklock, Sunderland. 3, E. Horner. *Ac*, G. Saddle, R. H. Blacklock.

RARRS.—*Cock or Hen*.—1 and 2, E. Horner. *Ac*, H. Yardley, N. Suggett, E. Mawson, J. Thresh.

TUMBLERS.—*Almond*.—*Cock or Hen*.—1, W. & H. Adams. 2, H. Yardley, Birmingham. *Ac*, T. Horman, A. & W. H. Silvester. 3, S. Lawson. *Any other variety*.—*Cock or Hen*.—1, W. & H. Adams. 2, E. Beckwith. *Ac*, E. Mawson (Bald, Bearded), W. H. Twedale (Blue Bald), E. Horner, E. Beckwith. 3, A. and W. H. Silvester, T. Horman.

OWLS.—*Cock or Hen*.—1, A. Simpson, Rochdale. 2, J. Thresh. *Ac*, E. Mawson, G. Alderson, J. Hainsine, E. A. Thornton, E. Horner. 3, G. Alderson, E. Beckwith.

TURBINS.—*Cock or Hen*.—1, E. Horner. 2, E. A. Thornton, Hull. *Ac*, T. P. Carver. *Ac*, G. Alderson, E. Horner. 3, G. Alderson.

NUNS.—*Cock or Hen*.—1 and 2, E. Horner. *Ac*, H. Yardley, T. P. Carver.

MAJESTIES.—*Cock or Hen*.—1, E. Horner. 2, J. B. Bowdon, Blackburn. *Ac*, M. Ord, J. B. Bowdon, P. Wilson, W. & J. Wetherill.

JACOBINS.—*Cock or Hen*.—1, G. Alderson, West Hartlepool. 2, T. E. Collinson, Ripon. *Ac*, T. P. Carver, W. H. Twedale, J. Thompson.

ANTWERPS.—*Cock or Hen*.—1, H. Yardley. 2, J. Stanley, Blackburn. *Ac*, W. Clark, E. Mawson, J. Hainsine, S. Box, W. Ellis.

FANTAILS.—*Cock or Hen*.—1 and 2, E. Horner. *Ac*, J. Walker. *Ac*, J. F. Lovelidge.

TRUMPETERS.—*Cock or Hen*.—1, E. Horner. 2, F. S. Barnard, Tottenham. *Ac*, E. A. Thornton, E. Beckwith.

CARRIERS.—*Cock or Hen*.—1, W. H. Johnson, Eccles. 2, J. Stanley. *Ac*, E. Mawson, T. E. Collinson, J. Stanley.

ANY OTHER VARIETY.—*Cock or Hen*.—1 and *Ac*, M. Ord (Ice, Blondinette), Durham. 2, E. Horner. *Ac*, H. Yardley, A. & W. H. Silvester, E. Horner. 3, S. Lawson (Ice).

SELLING CLASS.—*Single Bird*.—1, G. Saddle (Carrier). 2, J. Stanley (Barb). *Ac*, W. Boddy (Carrier), W. Sherwin, E. Horner, J. Jackson (Carrier), W. Ellis. *Ac*, G. Saddle (Carrier). 2, W. Addison, Ripon. 3, J. Thompson, A. F. Byford (Blue Turbils).

RABBITS.

LOP-EARED.—*Buck or Doe*.—1 and 2, A. Robson, Northallerton. *Ac*, J. S. Robinson, T. Myton. *Ac*, Messrs. Umpleby. *Any other variety*.—*Buck or Doe*.—1, C. & J. Illingworth. 2, T. Myton (Belgian Hare), York. *Ac*, J. S. Robinson (Silver Grey). *Ac*, H. Bradwell (Himalayan). 3, W. Benson (Himalayan).

CAGE BIRDS.

BELGIAN.—1 and *Ac*, W. Forth, Pocklington, York. 2, W. Shackleton, Ilkley. 3, T. Foster, W. Howard.

NORWICH.—*Clear*.—1, T. Tenniwood, Middlesborough. 2, C. Burton, Newgate, York. 3, G. Simpson. *Ac*, W. Forth.

YORKSHIRE.—*Clear*.—1, G. A. Watson, Harrogate. 2, W. Shackleton. *Ac*, R. Usher, G. A. Watson.

MARKED.—1, C. Burton. 2, W. Forth. 3, J. Young. *Ac*, T. Tenniwood. 4, T. Foster.

CANARIES.—*Any other variety*.—1 and 2, T. Humphrey, York. 3, W. Forth. *Ac*, T. Tenniwood.

SHEDS.—*Any other variety*.—1, W. Addison. 2, J. & H. Garbutt. *Ac*, W. Cowling. 3, W. Hall.

PARROTS.—*Any other variety*.—1 and 2, Mrs. Rollinson, Ripon. 3, H. Wescoe, Harrogate. 4, Williams & Son. *Ac*, W. Sherwin.

SELLING CLASS.—1, C. Lickley, Ripon. 2, W. Sherwin, Ripon. *Ac*, Miss Wells. *Ac*, W. Addison.

Mr. Dixon judged the poultry; Messrs. Hawley, Fletcher, and Robinson the Pigeons; and Mr. Hutton the Rabbits, in place of Mr. Cannan, who was ill.

BRISTOL POULTRY SHOW.

EACH of the great shows has its peculiar point of interest and attraction. At Oxford we look for the first appearance of some of the year's champions; at the Palace we gaze on the collective beauty of the country's poultry-yards till we are puzzled with its very variety, and think with pity on the Judges. At Birmingham we see, or try to see, fresh-caught from their park runs the representatives of many yards, which make their sole appearance there from the venerable antiquity of the Show. Bristol, too, has its special features. There we see in comfort and quiet, in a perfect light and arrangement, the pick of the great exhibitors' yards, for by this time rubbish has been weeded-out, and the inutility of showing second-class birds discovered. Several west-country exhibitors, too, reserve the best of their studs for competition there.

Bristol is now the third show in magnitude, and well does it deserve so to be. The minutest details of management appear excellent, and are a convincing proof of the power of one energetic will to organise where committees fail. Order seems to reign; there is no favouritism; all exhibitors are alike excluded before the opening of the Show, and hence none are disappointed and none grumble. The poultry world is greatly indebted to Mr. Cambridge for showing how things ought to be managed at shows generally, as well as for managing them at Bristol.

The poultry, save the smaller varieties, were ranged in one tier throughout the whole Show, and consequently could be fairly judged; the average quality was almost uniformly excellent through all classes; the judging was fairly good—we fear we cannot say more—and the visitors by no means so numerous as could be wished, or as the Show deserved. The birds were supplied with green food and looked happy, and not in the painfully feverish state we see them in the fetid atmosphere of Bingley Hall.

DORKINGS head the list with four classes for Coloured birds. The adults we thought decidedly better than the cockerels and pullets. The first cockerel is Mr. Hamilton's now far-famed winner, looking much better than he did at Oxford and at the Crystal Palace. Second a big bird, but we did not admire him; he is somewhat squirrel-tailed, and his toes much crooked. Third a good bird in many ways, but too red in the feet and not well clawed. Fourth we thought the second-best bird, dark in plumage with very white feet. On the whole we have seen better cockerel classes at Bristol. Pullets.—The pullet class, too, was hardly up to the mark. First a large and fine bird good all round. The two next awards we could not understand. Second was a nice bird in colour but not large, and with dark scaly legs. Third a large very dark bird with superlatively bad feet, little deformed, fourth toes high up the legs, and spurs behind. Fourth a fair bird in size and good all round. We should decidedly have put her second. Good birds of Mr. Beechey's and Mr. Walker's were unnoticed. Cocks.—This class was singularly fine in size, though a large proportion of the birds were out of condition and had sore or diseased combs. First-and-cup was a noble bird, a thorough Dorking all over, and in wonderful condition. Second not by any means his equal, but a fine bird with good points. Third not in first-rate condition, but a bony and good bird. A fourth (extra) prize

was given in this class to an immense fellow; his feet seemed the worse for wear, otherwise he must have been higher. Hens were another good class. First a beautiful bird all round, and rightly placed. Second another noble bird, not quite so good in feet. Third lighter in colour. We preferred Mr. Beechey's highly-commended bird to her.

Silver-Gray cocks were a poor class beyond the two first winners. First a very silvery and showy bird but with one spur behind. Second the Birmingham cup bird, not looking as he did, but having lost his sickles and apparently been in a fray of late. Third poor, speckled in breast and yellow in hackles. His owner's unnoticed bird was better. Hens were large and good. First a fine bird but with an ugly little straight comb. Second not so good as third in our opinion.

Whites.—First the Crystal Palace and Birmingham cup-winners, now very handsome with flowing sickles. Second had a handsome comb but no tail. Third was a curiosity, a large single-combed bird much ticked with colour on the back and hackle. We were informed on the highest authority that he was last year a celebrated winner in the Coloured classes, and went through this strange transformation at his last moult. This award opens a grand field for discussion, firstly as to whether a single comb is or is not a disqualification in a White Dorking; secondly whether coloured markings are admissible. We have never seen them before in a prize pen at any little local show. Hens.—First a long bird beautifully shown, but by no means the right bird in the right place. Second a square well-shaped Dorking, apparently rather antique. Third large and very white but with a broken tail. Her owner's unnoticed bird (the Palace cup hen) struck us as otherwise being the best bird in the class.

The COCHINS were very splendid, we should almost say they were the best classes in the whole Exhibition. Every variety was well represented, and we wonder if a better collection of adult White cocks and hens was ever seen before. Blacks, too, were admirable, and seem to be attaining the true Cochin shape with other good points.

In **Buff** cockerels the winner won the champion cup for the best pen in the Show. He is a good bird in every way, and we have described him before, but we should say there were many other single birds in the Exhibition which were at the least worthy of sailing in the same boat with him. The second and third were good cockerels and of nice colour. We liked all Mr. Burnell's three noticed birds immensely, and so we did Mr. Hodson's unnoticed one, and if we mistake not this latter was the Swindon cup cockerel. Buff pullets were capital; the winner was charming in colour, but a little too hooked for our taste. We never mind heavy feathering if only it curls well round, and so almost loses itself in the fluff. Second and third were very pretty birds. We liked, too, Mr. Burnell's very highly commended pen, and Mr. Crabtree's, 183. In old Buff cocks the first and second were both grand birds and well worthy of their places. They were in good condition and looked bright and strong, as we must say the Winkburn Hall birds generally do. Third was another very good old bird of grand shape and size. In hens the cup bird was too pale for our taste. She is a fine bird, but we like a richer colour. Second a good hen and in pretty condition. Third also a fine hen, and apparently quite young. Nearly every bird was noticed, and the quality throughout was wonderfully good.

In **Partridge** cockerels Mr. Shrimpton's bird is coming to the front. He is a beautiful chicken and the same, we believe, as we noticed at the Palace as likely to make a good one. The first was a good cockerel, large and light. The second we have commented on before, he is looking as well as ever. In the winning pullets the first was beautifully pencilled, but we thought her rather small. Second, a large bird and closely coming-up to her. Third, a neat bird and fairly marked. In old cocks the winners only call for remark, they were in fine condition, and we liked their position, though we believe others thought the first should have come in between Mr. Taylor's two birds. In hens the first won easily, and a grand one she was. We almost thought we should have come here for the cup Cochin hen. She is a model in shape and markings. Second and third were good hens and well shown. 209 (Rodbard), a very good bird, and we should think one useful for stock purposes.

White cockerels were weak. We thought the winner was well placed, but he is nothing wonderful. Second was the Oxford cup bird. He has lost some of the red he had on his wings, but he is not a good colour even now. Third we did not like, much preferring any of the other noticed birds. The fault throughout the class was bad colour and want of shape. Pullets were better. Mrs. Tindal's manager informed us that her winning bird had not been shown before. She is beautiful in colour. The second was Mr. Fowler's bird, and our ideas about her are well known. The third was poor in feathering, and narrow. To our mind the best pullet in the class was Mrs. Holmes's. We thought she was a perfect gem and should have won easily. Mr. Woodgate's pens were empty, as they were, too, in the cockerel class. 236 (Acton Tindal) unnoticed, was

the bird we believe which has been under dispute. White cocks were very grand. The winner was the Yarmouth bird, and very nice he is. He is a son of "Marquis," and was bred at Pembury. Second is a very fine old cock with a good head and chest, but a little tinged in colour. Third we believe was the Devonport cup bird. He is superb in colour and hackles. We must confess there were some other birds which we liked as well as any of the winners—namely, 247 (Bloodworth), 248 (Tindal), 254 (Procter), and 257 (Talbot), but the class was so even that we can well imagine the Judge being perplexed. Hens were almost better than the cocks, and made to our mind the best Cochin class in the Show. The winner is enormous, and grand in shape and feathering; *et cetera tout*, for her comb is hideous, and her colour bad. Second a neat hen and third here last year. Her comb is very beautiful, and rising four years she was more like a pullet than one or two birds which won in that capacity in other parts of the Show. Third was the bird which won the cup in 1875 for the best Cochin hen in the Exhibition, but she is not in good feather now. Among many other very excellent birds those calling for especial remark as being very good are Messrs. Whitehead's, Talbot's, and Percival's.

Black Cochins were splendid, the two best classes of the colour we ever saw. Introducing these two fresh classes must have paid Mr. Cambridge well. The winning cocks were all good. Mr. Darby's were in gorgeous bloom and very black throughout. Mr. Badger's birds were good and glossy, but not so large as the winners. In the next class hens won all the prizes. Pullets can do nothing in Cochins against hens, though we should say Mr. Turner's must have been near third place. We liked the first hen very much, and if she is sound in colour she is cheap at catalogue price. The noticed birds were all good, and also many of the unnoticed ones. We were very glad to see these handsome birds so looking-up, and still more so to find how well Cochins generally mustered, and that they appear to be as great favourites as ever. Since writing the above we learn that Mrs. Holmes's White pullet was left out of the prize list because the Judge thought her an elder bird. By January it is very difficult to know what is a pullet and what is not, but in this case we thought the bird was certainly an 1876 chicken, and much younger-looking than some of the other prize Cochin pullets in the Show.

SPANISH.—We always expect to see a good display of this variety here. The date of the Show suits them, and for a number of years some of the most successful exhibitors of Spanish fowls have resided at Bristol. The collection this year has, we think, equalled any of its predecessors. Possibly on previous occasions one or two grander specimens may have been produced, but the general quality and condition of the birds would, we thought, have compared favourably with any we have ever seen. Though we admired the beautiful manner in which the birds were shown, we desire our remark to be clearly understood as referring to those that were honestly shown, and not to those that had had the scissors so ingeniously applied to their combs. We noticed four instances in which, to lighten the weight and prevent the comb falling over, a large piece had been cut from the back, and in another case the serrations had been shaped to an approved pattern. We trust this matter will receive the attention of judges, and that the offenders will accept this warning, as we shall expose every case of this description that in future comes under our notice. **Cockerels.**—First (Hyde), pretty bird with a good quality of face, and a comb nicely curved over the back of the head, which showed no signs of giving way. Second (Miss Brown), a good bird, a little more open in the lobe than the winner, but the white was coarser, and the back of the comb not so well placed over the head as that of the winner. Pen 518 (Boulton), third, also a good-faced bird. We will describe his comb on a future occasion, if we ever have the opportunity of seeing him. Fourth, 529 (Jones), a neat bird that will improve and take a higher position at some future time. **Pullets.**—First (Goddard), the winner at the Alexandra Palace, and second at the Crystal Palace, a fine open-lobed bird, but she appeared to be a little crooked in the neck. Second (Chilcott), a large-faced bird, but inclined to be coarse. Third, same owner, was small in face, but the white was of beautiful quality. Fourth (Jones), larger in face, a good white but very wrinkled. Mr. Jackson's and Mr. Palmer's highly commended pens we liked, and they must have run the third and fourth pens very closely. **Cocks.**—First (Jones), a fine-faced bird. Second (Chilcott), in many points better, but his eyes appeared nearly closed, which doubtless lost him the first position. In other respects we considered him the best in the Spanish classes. Third (Jones), a good-faced bird, but his comb looked suspicious. Pen 554 (Mills), a Crystal Palace winner, we liked better. Hens.—First (Mrs. Alsopp), a beautifully-faced bird, and in fine condition. Second (Chilcott), almost as good. Third, a nice hen but not yet ready. 560 (Moore), the largest-lobed hen in the class, but out of condition. Pen 563 (Sillitoe), unnoticed, we thought should have been highly commended, she had many good points. We should have considered the

classes well judged had the manufactured combs been disqualified.

HAMBURGH.—The Spangled classes were far better than the Pencilled. We fear that the latter, especially the Silvers, are declining. It is a pity, for few birds are more beautiful, and none better layers.

Gold-spangled cocks.—First was a good bird all round; the cup for the best Hamburg cock justly went to him. Second pressed him hard; third a fairly spangled bird with a defect in the back of his comb. We preferred the very highly commended bird and Mr. Pickles' highly commended one. Hens.—Why Golden-spangled hens should in so many cases be out of condition while Silvers are blooming is always to us a mystery. First-and-cup well deserved her position; her moons are very round and evenly studded, and her condition and style admirable. Second a glossy and well-spangled hen. Third splendid in spangling; her comb and grizzly under feathering we did not like. The class was a good one, and among the highly commended were many birds worthy of prizes.

Silver-spangled cocks.—First was capital in comb with large spangling; he carried his tail in too pheasant-like a style. Second a bird with much smaller but evenly set moons. Third was a little yellow; in form we thought him the best bird in the class. The rest were not good. Hens.—First a marvel of spangling, which is as round and distinct as we have ever seen. Second a pretty bird, her spangles not large. Third a bird with large moons, but not evenly distributed over her.

Gold-pencilled cocks.—First a nice bird all round; his comb not sufficiently square in front. Second good in colour, but with a comb apparently doctored. Third not very even in colour. The very highly commended bird is very rich and dark in colour, but rather too square in form. Hens were mostly defective in breast-marking. First evenly barred, especially on the under parts. Second rich in ground colour. Third also good in ground colour, with small fine pencilling, but mossy towards the tail.

Silver-pencilled cocks made but a sorry muster. First a nice little bird, not particularly good in comb. Second coarse in comb, with sickles nicely laced. Third grizzly in tail, otherwise the best bird in the class. Hens.—First a well-barred bird, clear in hackles. No others were remarkable.

Black.—This variety is gradually rising in estimation; twenty cocks and nineteen hens were entered. The average quality was very high, though we saw no strikingly good birds. The first cock is lustrous, with a lovely comb, but not particularly good in carriage. We should ourselves have put out the second for an ugly unnatural comb. Third was a fair bird. Pen 670 (Mrs. George) contained a nice cock, his misfortune (?) being that his comb was honestly shown. When will Hamburg judges take this merit into consideration? Hens were a fine class, and very difficult to judge. First a bird excellent in style and colour, her comb not straight. Second a pretty bird. Third we thought a mistake; she has a bad comb and no style. One of the most prominent features of a Hamburg is the comb, and consequently this should not be overlooked in hens any more than in cocks.

GAME.—With a few exceptions we did not consider the Game classes here up to the usual standard. In the Reds Mr. Mathews won all the first prizes with birds that fully supported the owner's reputation. Mr. Dutton showed a good Black Red cockerel that was third in the pullet class. We did not like the second-prize hen; she has some good points, but was short in legs and wanted the style of a Game fowl. Any variety.—In the cocks Mr. Voisin was first with a good Duckwing, closely pressed by Mr. Mathews. Mr. Fitz-Herbert showed a good Pile here unnoticed; had he been in condition we think he would have found his way to the prize list. In the class for hens all the prizes went to Duckwings; here again we much admired a Pile shown by Mr. Fitz-Herbert.

MALATS.—These formed two of the best classes of the breed we have seen for many months. There were close on forty pens; and really next year, Mr. Cambridge, with a little help you may almost venture to make classes for young and old birds as in Cochins and Dorkings, &c. The winner was a finely-grown cockerel, good in shape and style, and with a true Malay head. Second another good cockerel, smart and bright. Third went to a fine old cock, but he had evidently been fighting and did not show to advantage. Among the other birds Mr. Hinton and Mr. Payne sent good cockerels, both hard in feather and good in head. A very nice pullet won in the next class; she was the stamp of bird we admire. Second and third were strongly-made good birds, but one or two of those noticed were closely treading on their heels. There were a number of birds very light in colour. Of course they may be exhibited of any colour in an open class, but our choice is for the Dark birds, they look so much richer and handsomer. We congratulate, however, Malay fanciers on their final appearance in 1876, even if they have been but poorly represented at the earlier shows of the year.

POLINE.—Gold and Silvers and Blacks were all good, and

all represented in the prize list. Both the two section cups came here also. The quality was exceedingly good, and apparently the three dozen pens entered were the cream of former shows. In cocks Mr. Beldon's old champion looked magnificent. Second went to another Silver almost equal to the cup bird. Third a very nice Golden, rich in colour and good in crest. Mr. Unsworth had a good Black highly commended. The noticed birds were all worthy of praise, and would have won in difficult competitions at most shows. In hens a Silver again won, a marvel in crest, markings, and shape. Second a good Golden, nice in colour; and third a superb Black, as good a bird as we ever saw of the colour. Five more birds were very highly commended, and five more highly commended, so this will show there was some quality, and the Judge had some work before him.

FRENCH.—Houdans.—First (Wood) a fine bird with good crest. Second (Vallance) a well-marked, nice-shaped bird. Third (Scott) a good bird, but we think we should have given the preference to pen 901 (Vallance), highly commended. Hens.—First (Thomas) a grand bird, with splendid crest. Second (Vallance) a neat, evenly marked bird. Mr. Quibell and Mr. Lake showed pens, highly commended, that we liked very much. Any other variety.—In cocks Mr. Outlack was first with a grand Crève, and in hens Mr. Stevens secured the first prize with a bird of 1875. Mr. Crabtree's second-prize hen was a splendid bird, and must have run the winners very close.

BRAMMAS will be noticed next week.

LEGHORNS.—This breed had four classes and made a nice show. They seem to boast a fair party of admirers, who we think most plucky to get classes for their birds and do their best to establish them as a permanent breed. We think them started now, and they will probably gain, not lose, ground; but like Silkies and such like they will never, we fear, be able to support classes everywhere, and will have to go into variety classes mostly, save at the large shows and where amateurs guarantee the prize money. The Browns were very good, the ears have improved very much, and the size too increased. Mr. Kitchin sent his old bird for admirers to see, as he has been the sire of so many of the winners in 1876, not only in Mr. Kitchin's name but in others. Mr. Brown had his imported cocks in the list, and nicely they looked.

Whites were very good, but so many were shown dirty. It is the greatest disadvantage, for White birds depend so much upon cleanliness. We thought more size was wanted in the cocks especially. Here, too, the earlobes have much improved.

MINORAS.—Seventeen pens were entered, of these the majority were Black. Hens were better than the cocks. We conclude their combs are easier to obtain. The winning Blacks were very smart and stylish. Mr. Williams's pens were also capital and nicely shown. The first hen had a huge comb, it looked like a beefsteak almost, and quite hid the rest of her head. Second and third good birds and bright in colour. We hear on all sides wonderful accounts of the laying powers of these birds, and should imagine they will soon be more generally found in other parts of England than the west, where they now mainly seem to exist.

THE VARIETY CLASS.—Here was the usual pot-pourri, but not quite so well mixed as usual. In cocks a pretty Sultan was first; a nice Cuckoo Coochin which we preferred to the Sultan second; and a neat Silky third; the latter good in comb, which is very rarely found in cocks. Hens were a very interesting class, a nice Cuckoo Coochin first, a Sultan second, and a lovely Silky pullet third, of what we call a perfect size, but much larger than Mr. Darby considers his usual type. More Cuckoo Cochins, Cuckoo Bantams, a Sultan, and an Andalusian were highly commended, all good of their breeds; also a pretty Indian Jungle pullet with a beautiful breast.

BANTAMS.—Game Bantams do not hold their own; they are both larger, and the Reds less rich in colour than they were some years ago, still as a rule the winners show true gamy style. The cup for the best pair of Game Bantams went to the first pair in the class for Reds; they were Black Reds, the cocks very stylish, not small. Second were Black Reds again, smaller birds, but the cock deficient in wing-colouring. Third were Brown Reds. In the class for any other variety Piles were first; Duckwings of very high carriage second; Duckwings third.

Black Bantams were a good class of seventeen entries. The cup pair were longer in legs than we like, but the cockerel very good in comb and a pretty bird. The second cockerel was, like many others, devoid of side tail feathers, a great deficiency in our judgment. The cockerel in the third-prize pen had better sickles, but not so natural a comb as the first and second.

Sebrights.—First were Silvers, very white in ground colour, evenly and beautifully laced. Second Silvers again, more heavily and less precisely laced. Third well laced and good Golden; we should have put them second.

Whites are looking up again, though they do not reach the Black standard; Mr. Tearle held his old place with a pretty pair. Second a nice pair but rather large. Third small but far too high in combs.

Game Bantam cocks.—First a neat Black Red, but by no means small. Second a very dirty Pile. Third a Black Red, deficient in tail. We much admired Mr. Nelson's very highly commended Black Red.

There were two Selling classes for Bantams. Sebrights at any moderate price seem always to find purchasers. In cocks first was a Silver-laced bird, a trifle large, but a bargain if sold at anything like the catalogue price. Second an indifferent Black. Third a pretty Black Red. In hens fair Blacks were first, Black Reds second, and third were Silver Sebrights with buff ground colour.

Waterfowl.—Only five pens of Aylesburys, with all the winners good. The first and second very even in quality. Rouens made a score of pens, good in colour and shape most of them, but the cup pen a-head. Second, also, very good and well made, and not far off the cup pen. Third again a good pen. Mr. Pope and Mr. Parlett had good pens highly "condemned." Black Ducks were lovely. The prizes were divided among the three cracks. We think it was almost a toss-up which won the cup of the first or second-prize pens, for both were beautiful. Notices were few, for we thought one or two more pens deserved them. What would have won here five years ago would not get a second look from a judge in the present day, for the colour has been got so beautiful, and the size so much reduced. Still we doubt if the great exhibitors are wise to monopolise all the prizes at every show; we fear it will bring bad, not good, fruits. The fancy Ducks were also beautiful, and the whole class noticed. It is impossible to criticise, the birds were so even, most of them. We never could make out how the winners are selected in such company.

Geese only eight pens, all good. Of these two contained the handsome Chinese of Mr. George.

Turkeys only six pens. Surely Christmas must have been too much for them.

PIGEONS.

The history of Bristol Show resembles that of many a persevering Englishman. Such a one determines to persevere whatever happens. For some years no success, or success outwardly, but the purse empty. Still he goes on; he won't give in. Timid friends say, "You had better leave off;" but no; his answer is, "I will succeed at last," and he does. So of Bristol Show—pecuniary loss for eight years, the favourable turn comes on the ninth, and full success on the tenth. I enter the Hall, and find it, as always, the best place of exhibition out of London that I am acquainted with: the arrangements good, the provision for the Pigeons suitable—a small vessel for food as well as water, which is specially excellent for the heavily wattled Pigeons who cannot see to pick up their food from the floor. I have noticed the temperature of the Hall as being suitable, and especially not being variable. This brings me to say a word about the Birmingham Show. The Pigeons are placed in an atmosphere so intensely hot in the evening that I, enjoying heat of all things, have been obliged to leave the gallery; then it becomes early in the morning bitterly cold. So long as the Committee insist upon placing the Pigeons where they now place them, so long fanciers should refuse to send their birds, and therefore the Show comes to an end. In a better place it may go on, but, of course, can never be what once it was before the London shows were in existence. I am no exhibitor; I simply write from kindly feeling for the poor birds. No word of condemnation can, happily, be written as regards the Rifle Drill Hall, Bristol.

The **Pigeons** numbered about six hundred. Carriers (cocks, Black or Dun).—First-and-cup magnificent in colour and in beak-wattle. The second, in my judgment, not so good as the third. The class, as a whole, superior. Carrier hens.—First a good stout Dun. Carriers any other colour, which means, of course, Blue, the hens better than the cocks, the first of the latter being a wonderful bird. Carriers any colour, bred in 1875, brought out as first-and-cup a thoroughly good-going cock, Dun, and such a Dun, indeed, both as to colour and shape, is one of which its owner, Mr. W. Siddons, may well be proud. Pouters.—These birds are advancing in England, and becoming far more numerous. Mr. Bullen's Black cock first, as it deserved; there is no doubt of its superiority. A bad-coloured Black, almost a half-blue, but with fine limbs, was second. Third a good Blue. No. 1555 (Fulton) a bird of excellent colour. Black or Blue hens.—First-and-cup a fine bird, but the crop not globular, but too oblong. Second a charming Blue and much better-shaped crop. Among any other colour I must notice the first White cock, a very graceful bird, but wants more crop. No. 1570 a good Red, and 1569 a nice White. Hens, any other colour.—First a wonderful bird if in fair condition. Second Mrs. Ladd's graceful White, but wants crop. Third a good Yellow hen. The Almond Tumblers good classes, both cocks and hens, and colour richer than formerly. Shortfaces.—First a lovely Kite (J. Baker). Foreign Owls again not so numerous as their English cousins, but a nice and variously coloured lot, including one, No. 1611, a White with a blue tail. Barbs few but good, and none repulsive-looking from old age. Mr. Maynard's hen

(first cup) the cream of the lot. The young Barbs were very promising. The Trumpeters, out of ten pens all but two were very good. Jacobins, Red or Yellow.—Here a country fancier, Mr. Heath of Calne, secured a great triumph with a bird that had never been shown, a Red cock; he was first, and Mr. Fulton's Yellow, the champion of the Crystal Palace, was third. Oh, what changes men and Pigeons have to undergo! The second a Red with a somewhat ragged hood. No. 1557 a charming bird (Fulton). Jacobins, any other colour.—First a Black, good in colour but poor in hood. Second a deal the best, being a good Jacobin (Black), but probably the stained beak (lower mandible) made him second only. Third, hood too far back. Where were the Whites, for none appeared? Fantails a good class. Turbits very strong classes. First (Red or Yellow) a very nice Yellow. Among the Any other colour, first-and-cup a capital Black; second a pretty Silver; third an equally good Blue. English Owls.—First-and-cup a noble Blue, a thorough English Owl, fine, large, bold-looking. Second a good Silver. One, No. 1744, too small for an English Owl. Of the Nuns several pens were empty, but those that were full were deserving. Magpies very numerous, chiefly to be noted by an excellent Yellow, second-prize, being marked by its owner at only a guinea. Dragons, very large entries, as now usual in England. No one could withhold his tribute of admiration at these excellent birds. Blues and Yellows were particularly good. Mr. Richard Wood was very successful in all classes. Crowds of Antwerps; but I could not but ask myself, Where do the Shortfaces end, and the Longfaces begin? There was an interesting class of Flying Tumblers, a variety needing encouragement. Among them was a Cumulet, which is scarcely a Tumbler. Any other variety.—First Mr. Fulton's Black Turbitten; third a most lustrous Archangel; third a fine Runt. This was so good a class that more than half the birds were noticed. There were two large Selling classes, which probably paid the Committee better than their owners.

Such was the Bristol Pigeon Show. Good birds shown in a good place, and few deaths to follow, for the weather was not cold for their transit, and the exhibition-room, as I have before remarked, in every way suitable.—WILTSIRE RACON.

DORKINGS.—Coloured.—Cockerel.—1, Rev. H. F. Hamilton, Combe St. Nicholas, Wiltshire. 2, E. Barnett, Eniton. 3, Viscount Turnour, Fawcett. 4, R. W. Beachy, Kingscliff. 5, R. W. Beachy, W. Harvey, J. Walker. 6, O. E. Cresswell, Pullet. 1, J. White, Northallerton. 2, Miss J. Milward, Newton St. Loe. 3, E. Feating, Newtown. 4, A. Jackson, Broughton. 5, E. Hyda, J. L. Lowndes.

DORKINGS.—Coloured.—Cock.—Cup and 1, F. Parlett, Galleywood, Chelmsford. 2, W. Cople, Ekeston. 3, R. W. Beachy. 4, Rev. H. F. Hamilton. 5, R. W. Beachy. 6, F. Parlett. 7, J. Walker, Spring Mount, Rochdale. 8, Rev. H. F. Hamilton. 9, J. White, Rev. E. Bartrum, R. W. Beachy, P. Ogilvie, E. Ponting, W. H. Denison.

DORKINGS.—Silver Grey.—Cock or Cockerel.—1, L. Wren, Lowestoft. 2, O. E. Cresswell, Bagshot. 3, W. W. Rutledge, Kendal. 4, Hen or Pullet. 1, J. Walker. 2, W. W. Rutledge. 3, O. E. Cresswell. 4, O. E. Cresswell, Mrs. Bidder, W. H. Denison.

DORKINGS.—White.—Cock or Cockerel.—1, O. E. Cresswell. 2, W. Badger, Little Wymondley. 3, R. W. Beachy. 4, Hen or Pullet. 1, Mrs. A. Tindal, Aylesbury. 2, A. Darby, Shrewsbury. 3, O. E. Cresswell.

COCHINS.—Cinnamon or Buff.—Cockerel.—Cup and 1, Mrs. A. Tindal. 2, R. P. Percival, Northenden. 3, G. H. Proctor, Durham. 4, J. Cattell, W. A. Barnell, Southwell. 5, W. P. Ryland, W. A. Taylor, Mrs. Allsopp, Capt. E. Mills, W. A. Barnell. 6, Pullet. 1 and 2, W. A. Bindley, Edgaston. 3, Rev. G. Hodgson, W. A. Barnell. 4, Mrs. Allsopp, Capt. T. S. Robin, Mrs. A. Tindal. 5, W. A. Barnell, W. A. Barnell.

COCHINS.—Cinnamon or Buff.—Cock.—1 and 2, W. A. Barnell, Southwell. 3, J. Walker. 4, J. Bloodworth, W. P. Ryland, J. Cattell, W. A. Taylor, Henry Lingwood. 5, Cup and 1, G. H. Proctor. 2, J. Cattell, Birmingham. 3, R. P. Percival. 4, A. J. Symonds, W. A. Barnell. 5, R. Fowler, J. Bloodworth, Mrs. Allsopp, C. Bloodworth, W. P. Ryland, J. Walker. 6, A. Darby, R. P. Percival, J. Johnson.

COCHINS.—Brown or Partridge.—Cockerel.—1, J. Ashcroft, Liverpool. 2 and 3, Mrs. A. Tindal. 4, G. Shrimpton, Leighton Buzzard. 5, Mrs. Atterton, Mrs. A. Tindal, R. P. Percival, G. Shrimpton. 6, Pullet. 1, R. P. Percival. 2, Mrs. A. Tindal, Aylesbury. 3, F. Duke-Laurie, Alton. 4, J. N. C. Pope, J. Ashcroft, Liverpool.

COCHINS.—Brown or Partridge.—Cock.—1, Mrs. A. Tindal. 2 and 3, W. A. Taylor, Manchester. 4, F. Wilson, Hen. 1, Mrs. A. Tindal. 2, J. Ashcroft. 3, R. P. Percival. 4, J. E. Rodbard, T. Aspin, W. A. Taylor, G. Shrimpton, Mrs. Foy.

COCHINS.—White.—Cockerel.—1, W. A. Barnell. 2, Mrs. A. Tindal. 3, J. H. Nicholls, Lowestoft. 4, W. A. Barnell, J. H. Nicholls, J. Turner, G. Shrimpton. 5, Pullet. 1, Mrs. A. Tindal. 2, J. K. Fowler, Aylesbury. 3, T. H. Waterman, Ac. T. H. Waterman.

COCHINS.—White.—Cock.—1, A. Darby. 2, Mrs. J. T. Holmes, Wells. 3, T. H. Waterman. 4, J. A. Tindal. 5, J. A. Tindal. 6, J. A. Tindal. 7, Capt. G. F. Talbot. 8, W. A. Barnell. 9, Bloodworth. 10, Capt. G. F. Talbot. 11, W. F. Salder. 12, Hen. 1, W. A. Barnell. 2, J. Turner. 3, Bath. 4, Mrs. A. Tindal. 5, J. N. Whitehead. 6, R. P. Percival. 7, Capt. G. F. Talbot. 8, J. Bloodworth. 9, Rev. R. S. Woodgate. 10, Bloodworth. 11, Capt. G. F. Talbot. 12, Mrs. A. Tindal, Aylesbury.

COCHINS.—Black.—Cock or Cockerel.—1 and 2, A. Darby. 3, E. Pritchard, Tottenham. 4, W. Badger, J. Turner, G. Forster. 5, Hen or Pullet. 1, W. G. Holt. 2 and 3, N. Cook, Manchester. 4, R. B. Good, W. G. Holt, T. Aspin, J. Turner, W. Badger, J. Day, A. Darby, W. Whitworth, Jun.

BRAMMAS.—Dark.—Cockerel.—3, Hon. Mrs. A. B. Hamilton, Ridgmont. 2, Horace Lingwood, Creeting. 4, J. Lyon, St. Helens. 5, R. P. Percival, J. Gilbert. 6, L. Wright, D. Moulson, P. F. Le Saeur, Hon. Miss Douglas-Pennant. 7, J. Rimmer, G. H. Whitehouse. 8, Pullet. 1 and 2, R. P. Percival. 3, Horace Lingwood. 4, Newham & Manby, Wolverhampton. 5, Rev. J. D. Peake. 6, Hon. Miss Douglas-Pennant. 7, H. B. Morrell, Hon. Mrs. A. B. Hamilton. 8, R. B. Wood, J. Walker, Horace Lingwood, Newham & Manby, Rev. J. D. Peake. 9, J. Walker.

BRAMMAS.—Dark.—Cock.—Cup and 1, Horace Lingwood. 2, T. F. Ansell, Cowley Mount. 3 and 4, Hon. Miss Douglas-Pennant, Bangor. 5, E. Kendrick, Jun. 6, H. B. Morrell, Lady Chetwynd. 7, T. A. A. Hen. 8, Cup, 1 and 2, Newham & Manby. 3, Rev. J. D. Peake, Latham Vicarage, Chertsey. 4, Horace Lingwood. 5, Bamford, J. F. Smith. 6, T. F. Ansell. 7, J. Evans, E. Kendrick, Jun. 8, H. B. Morrell, T. F. Ansell, Hon. Miss Douglas-Pennant, Dr. J. Holmes, E. Pritchard.

W. A. Bryson. 2, J. M'Nab, Belfast. 3, J. M'Laren, Greenock. 4, G. Grant, Glasgow. 5, W. Thom.
PERALD BUFF.—Cock—1, J. M'Nab. 2, J. Smith. 3, T. Scott, Carlisle. 4, R. Bryson. 5, N. M'Lean, Glasgow. **Hen**—1, T. Scott. 2, J. M'Laren. 3, J. Lashlan, Kilmarnock. 4, W. Thom. 5, J. Ferris.
FOAM.—Yellow or Buff.—Cock—1, T. Scott. 2, R. Baxter, Bath. 3, D. Dunlop. 4, G. Grant. **Hen** and special, A. Steel, Glasgow. 2, J. W. Bryson, Paisley. 3, P. M'Donald, Glasgow. 4, H. Archibald, Dairy.
GREEN.—Yellow or Buff.—Cock—1, J. Pettigrew. 2, W. Thom. 3, W. M'Intyre. 4, J. Knox. **Hen**—1, H. Webster, Kilmarnock. 2, J. Kelly, Paisley. 3, T. Cooper. 4, B. White, Paisley.
GOLDEN PHEASANT.—Yellow or Buff.—1 and 2, J. Thorpe, Dumfries. 3, J. Black. 4, J. M'Pherson.
GOLDEN PHEASANT.—1 and 2, T. Revis, Glasgow. 3, D. M'Kay, Paisley. 4, W. Arthur, Paisley.
HENS ON FOSKROW BIRD—1, W. Whitehead, Paisley (Cockatoo). 2, W. Clark, Machan, Larkhall. 3, R. M'Pherson, Govan. 4, J. M'James, Paisley.

ABERDEEN CANARY SHOW.

The twentieth annual Exhibition of the Bon-Accord Ornithological Society took place at the Music Hall Buildings on Friday and Saturday last, the 31st of December and 1st of January. The entire arrangements were admirable, and reflect the greatest credit to those who had the arranging and carrying out the Exhibition, which was the best yet held in Aberdeen. The weather was beautifully fine, and many were induced to visit the Exhibition.

About 840 birds were shown for competition alone, and two well-known exhibitors from Sunderland and Norwich entered freely, although the distance was so great. Another case of a painted or artificially-coloured Norwich Canary turned up, the exhibitor being James Blair, of 111, Hadden Street, Woodside, Aberdeen. We are determined to expose all cases of this kind, with a view to check the abominable practice. The following are the awards:—

COMPETITION CONFINED TO MEMBERS OF THE SOCIETY.

BELGIANS.—Clear or Ticked Yellow.—Cock—1 and 2, J. Coutts. 3 and 4, R. Sutherland. **Hen**—1, A. Black. 2, A. Black. 3, Blair. 4, J. Coutts. **Hen**—1, 2, and 3, R. Sutherland. **Hen**—1, Blair. 2, J. Coutts (2).
BELGIANS.—Clear and Ticked Buff.—Cocks—1, J. Blair. 2, J. Duff. 3 and 4, R. Sutherland.
NORWICH.—Clear Yellow.—Cocks—1 and 2, J. Bisset. 3 and 4, G. Chalmers. **Hen**—1, F. Lyon. 2 and 3, W. Silver. 3, J. Duff.
NORWICH.—Clear Buff.—Cocks—1, J. Bisset. 2, 3, and 4, G. Chalmers. **Hen**—1, W. Silver. 2, G. Chalmers. 3, Bisset. 4, P. Lyon.
NORWICH.—Marked Yellow.—Cock or Hen—1 and 2, W. Silver. 3, A. Smith. **Variegated Yellow.—Cock or Hen**—1 and 2, J. Taylor. 3, A. Gordon. 4, W. Silver. A. Gordon.
NORWICH.—Marked Buff.—Cock or Hen—1, G. Ross. 2 and 3, P. Lyon. **Variegated Buff.—Cock or Hen**—1, P. Lyon. 2, G. Chalmers. 3, J. Blair. 4, J. Taylor. 5, J. Duff.
ORIENTAL.—Yellow or Yellow Marked.—1 and 2, G. Ross. 3, J. Bisset. **Buff or Buff Marked.**—1, 2, and 3, W. Silver. 3, J. Bisset.
GREEN.—Cock or Hen.—1, 2, and 3, A. Gordon. 4, P. Lyon.
SCOTCH FANCIER.—Clear or Ticked.—Cocks—1, 2, 3, and 4, P. Lyon. **Hen**—1, 2, 3, and 4, P. Lyon. 3, J. Coutts.
LIRAZA.—Golden-spangled.—Cock or Hen.—1, 2, and 3, J. Coutts.
CINNAMON.—Jongue.—Cock or Hen.—1, 2, and 3, P. Lyon. 3 and 4, G. Ross. **Buff.—Cock or Hen.**—1 and 2, G. Ross. 3 and 4, J. Duff.
GOLDEN PHEASANT.—Cocks.—1 and 2, A. Black. 3, J. Taylor.

OPEN TO ALL COMERS.

BELGIANS.—Clear or Ticked Yellow.—Cocks—1, 2, and 3, J. Bisset. 4, J. Coutts. 5, J. Blair. 6, R. Sutherland. **Hen**—1, 2, 3, and 4, J. Bisset. 5, J. Blair. 6, R. Sutherland.
BELGIANS.—Clear or Ticked Buff.—Cocks—1 and 2, J. Bisset. 3, R. Sutherland. 4, J. Bisset. 5, R. Sutherland. 6, J. Bisset. 7, R. Sutherland. 8, J. Bisset. 9, R. Sutherland. 10, J. Bisset. 11, R. Sutherland. 12, J. Bisset. 13, R. Sutherland. 14, J. Bisset. 15, R. Sutherland. 16, J. Bisset. 17, R. Sutherland. 18, J. Bisset. 19, R. Sutherland. 20, J. Bisset. 21, R. Sutherland. 22, J. Bisset. 23, R. Sutherland. 24, J. Bisset. 25, R. Sutherland. 26, J. Bisset. 27, R. Sutherland. 28, J. Bisset. 29, R. Sutherland. 30, J. Bisset. 31, R. Sutherland. 32, J. Bisset. 33, R. Sutherland. 34, J. Bisset. 35, R. Sutherland. 36, J. Bisset. 37, R. Sutherland. 38, J. Bisset. 39, R. Sutherland. 40, J. Bisset. 41, R. Sutherland. 42, J. Bisset. 43, R. Sutherland. 44, J. Bisset. 45, R. Sutherland. 46, J. Bisset. 47, R. Sutherland. 48, J. Bisset. 49, R. Sutherland. 50, J. Bisset. 51, R. Sutherland. 52, J. Bisset. 53, R. Sutherland. 54, J. Bisset. 55, R. Sutherland. 56, J. Bisset. 57, R. Sutherland. 58, J. Bisset. 59, R. Sutherland. 60, J. Bisset. 61, R. Sutherland. 62, J. Bisset. 63, R. Sutherland. 64, J. Bisset. 65, R. Sutherland. 66, J. Bisset. 67, R. Sutherland. 68, J. Bisset. 69, R. Sutherland. 70, J. Bisset. 71, R. Sutherland. 72, J. Bisset. 73, R. Sutherland. 74, J. Bisset. 75, R. Sutherland. 76, J. Bisset. 77, R. Sutherland. 78, J. Bisset. 79, R. Sutherland. 80, J. Bisset. 81, R. Sutherland. 82, J. Bisset. 83, R. Sutherland. 84, J. Bisset. 85, R. Sutherland. 86, J. Bisset. 87, R. Sutherland. 88, J. Bisset. 89, R. Sutherland. 90, J. Bisset. 91, R. Sutherland. 92, J. Bisset. 93, R. Sutherland. 94, J. Bisset. 95, R. Sutherland. 96, J. Bisset. 97, R. Sutherland. 98, J. Bisset. 99, R. Sutherland. 100, J. Bisset. 101, R. Sutherland. 102, J. Bisset. 103, R. Sutherland. 104, J. Bisset. 105, R. Sutherland. 106, J. Bisset. 107, R. Sutherland. 108, J. Bisset. 109, R. Sutherland. 110, J. Bisset. 111, R. Sutherland. 112, J. Bisset. 113, R. Sutherland. 114, J. Bisset. 115, R. Sutherland. 116, J. Bisset. 117, R. Sutherland. 118, J. Bisset. 119, R. Sutherland. 120, J. Bisset. 121, R. Sutherland. 122, J. Bisset. 123, R. Sutherland. 124, J. Bisset. 125, R. Sutherland. 126, J. Bisset. 127, R. Sutherland. 128, J. Bisset. 129, R. Sutherland. 130, J. Bisset. 131, R. Sutherland. 132, J. Bisset. 133, R. Sutherland. 134, J. Bisset. 135, R. Sutherland. 136, J. Bisset. 137, R. Sutherland. 138, J. Bisset. 139, R. Sutherland. 140, J. Bisset. 141, R. Sutherland. 142, J. Bisset. 143, R. SPECIAL PRIZES.

Ladies' Cup for best bird in Section I, gained by R. Sutherland.
 B. Reid & Co.'s prize of One Guinea for the best Yellow Belgian in Section I, gained by R. Sutherland.
 Society's Cup for most points in Section I, gained by P. Lyon.

James Cocker & Sons' prize of 7s. 6d. for second in points, Section I, gained by W. Silver.
 Society's Cup for most points in Section II, gained by W. B. Howell.
 Silver Medal from the Members for best Don in the Exhibition, gained by P. Lyon.
 Silver Medal from the Members for best Goldfinch Male in the Exhibition gained by Capt. J. Gordon.
 Silver Medal from the Members for best Goldfinch in the Exhibition, gained by A. Burns, jun.
 Silver Medal from a Member for best Bullfinch in the Exhibition, gained by W. Dean.

JUDGE.—Mr. G. J. Barnesby, Derby.

THE PRIZE CHESHIRE WAX-GUIDE-MAKING

man may easily supply guides to a hundred frames in an hour.—
JOHN HUNTER, *Eaton Rise, Ealing.*

THE WONDERS OF A BEE HIVE.—No. 2.

My first letter on this subject touched the fact that both the sovereign and subjects of a bee hive are produced and producible from the same kind of eggs. Though both are hatched from one kind of eggs they are not treated alike, or hatched in the same kind of cells. The cells in which queens are reared are indeed regal palaces compared to the cells of working bees. Royal cells occupy much more space, are very differently constructed, and with a great expenditure of wax. Royal cells are vertical in form, and, therefore, queens are reared and hatched with their heads towards the floor-board, whereas workers are reared and hatched in horizontal cells built closely together, with the smallest possible expenditure of wax.

Eggs in royal cells become worms (very small maggots) in three days, when they may be easily seen floating in a milk-like substance at the bottom of the cells. The royal infants grow uncommonly fast for five days, completely filling their cradles by the end of that time, when the bees put beautiful lids over them, thus sealing them up. In about six or seven days more (fourteen altogether) they come to maturity. But before they are born the tragedy of their life begins, and a wonderful tragedy it is. When an old queen dies or goes away with a swarm the bees invariably rear more than one queen; generally speaking they rear from three to five queens, and sometimes more. They come to perfection about the same time, and with dispositions to fight and murder one another. These princesses have no sisterly feelings, and can brook no rivals. The one first matured in her cell gives distinct intimation before she is born that she will claim the throne of the hive by uttering some strange and peculiar sounds. She calls "off, off, off," again and again, and as her calls and claim remain unchallenged she pushes the coverlet of her cradle-cell aside, and with a dignity becoming royalty asserts herself the queen of the hive. She is heartily welcomed by the community, and is received and recognised as their rightful sovereign. The sister princesses speedily come to maturity, and begin to call "off, off," in their cells. These sounds indicate rivalry and opposition, which much provokes the reigning queen, and makes her run to and fro and up and down the hive with unquenchable deadly hate and murderous intentions. She now calls "peep, peep," first in one place and then at another; meanwhile her sisters accept her challenge by repeating their "off, off," from their cells. This "piping" of the queen and princesses is a wonderful feature in the history of bees. What is it for? Who can explain or understand it? It is doubtless a wise and necessary arrangement in the economy of bees, though its mysteries are too deep for the limited powers and perception of men.

The piping of queens, if continued, heralds the departure of second and third swarms from hives. The queen is often called "the sovereign," and the bees "the subjects;" but it should be known that the monarchy of a bee hive is a very limited one, for the working bees sit in the highest council chamber and there decide the destinies of the community, including even the birth, life, and death of queens. Very well; when the bees decide that second swarms will not be sent off they speedily stop the piping. The princesses are killed in their cells and cast out of the hive. If swarming be decided on in the high council the piping is continued for three days and nights, when, weather permitting, a second swarm issues from the hive. We have known a case of continued piping for seven days. The queen and princesses kept answering one another constantly for a whole week, night and day. The bees kept the reigning queen from attacking the princesses (unborn), and they were secured, watched, and confined to their cells like dogs to their kennels. And never did dogs bark so continuously as did these confined queens. Just one word in passing on the fact that these young creatures found no time for sleep during the whole week. Sleep is impossible to queens during the piping season. If they can do without sleep then when are they more likely to require it?

The interesting incidents—the fuss and pageantry connected with the introduction of queens to the world—are numerous and difficult to describe. Queens have stings, blunt and curved, which they never use but in royal battles. No amount of provocation or pressure by human hands ever cause them to use their stings. Human breath is most offensive to working bees, but queens may be safely rolled under the tongue and held in the mouth of any person. I shall leave this part of my subject by giving the reader an account of a royal battle seen and described by a lady. "The bees had built six queen cells, and in about twelve days the first queen was hatched. As soon as she was fairly born she marched rapidly, and in the most energetic manner, over the combs, visited the other cells in which were the embryo queens, and seemed at times furious to destroy them. The workers, however, surrounded her, and prevented such wholesale murder. For two days she was intent upon her fall purpose, kept in almost continuous motion to

effect it. On the fourteenth day the second queen was ready to come out, piping and making noises to attract attention. A part of the bees then seemed to conclude that it was time to take the first queen with them and swarm, but by some mistake she remained in the hive after the swarm had left. The second queen left her cell soon after the swarm had gone, and now there were two hatched queens in the hive. The workers were in a state of great uneasiness and commotion, seeming impatient for the destruction of one of them. The queens met, and the combat commenced in which one was to gain her laurels and the other to die. The battle was fierce and sanguinary. They grappled each other, and, like expert wrestlers, strove to inflict the fatal blow. For some moments the parties seemed equally matched. The bees stood looking calmly on the dreadful struggle. The battle, like all others, had its close; one fell on the field, and was immediately taken by the workers and carried out of the hive. The swarm was hived, but being without a queen, came rushing back, but was not in time to witness the fatal struggle."

The life of a queen bee to the community is of inestimable value. See what care and labour are bestowed in constructing royal cells; what a short time is required to hatch princesses; what peace and joy reign in a hive possessing a healthy queen; what affection is manifested for her by the bees—their uneasiness when she is out of their sight—their wall of lamentation when she is lost—their utter hopelessness, ruin and collapse when they have no eggs wherefrom to raise a successor!—
A. PETTIGREW.

REMARKS.

29th.—Fine morning, but no sun; overcast at night.
30th.—Dull and overcast throughout the day; very calm.
31st.—Generally dull, but bright sun at intervals; cloudy at night. On the whole the finest day in the week.
1st.—Dark, damp, and thick all day, with rain at and after 11 A.M. The temperature unusually steady.
2nd.—Rain at intervals all day, and at times very dark; rain also during the night.
3rd.—A little rain before 9 A.M. A warm damp day, a fine sunset, and starlight night.
4th.—Very dark early; rather bright for a short time about noon; damp and thick till 6 P.M., and then much finer.
The most remarkable feature of the week is the equability of the air temperature. From 9 A.M. on 26th to 9 P.M. on the 1st it only varied from 40.5° to 47.8°—G. J. SYMONS.

COVENT GARDEN MARKET.—JANUARY 5.

No recovery from last week, with the exception of late sorts of Peas, for which a good demand is now being felt. Some very fine samples of St. Michael Pines are now to be seen in the market, completely spoiling the sale of English ones.

THE MISTLETOE AND ITS CULTURE.

[This is the first part of a communication to the Maidstone Gardeners' Mutual Improvement Association by its Secretary, Mr. J. Kentish. The second part on the Holly will follow.]

HE Mistletoe is, as you are aware, an ever-green parasitical bush, found very rarely growing upon the Oak, but principally upon Apple trees, and in England is therefore more common in our cider counties. It is found on the Lime trees in Buckinghamshire, and on the Black Poplar in Surrey. In Jerusalem and Spain it is found on the Olive tree. The roots of the Mistletoe penetrate the bark of the tree on which it grows,

and extend themselves between the inner bark and the soft wood where the sap is most abundant. The roots of the Mistletoe, as the tree on which it grows advances in growth, become embedded in the solid wood. The root, however, in no way unites with the tree, save for the purpose of feeding its own plant from the sap; thus the effect of the Mistletoe upon the tree must be to injure the branch, particularly the part beyond the Mistletoe. This parasitical plant absorbs the ascending and descending sap and gives nothing in return; it solely robs, and is on that account not liked in orchards. This, I said, is a parasitical plant—i.e., it not only lives on another, but maintains its life by robbing of its sap the tree on which it grows; it is therefore more hurtful than many other plants growing on trees, which are termed Epiphytes, the difference being that these derive their nutriment from the decay of the outer bark or from the atmosphere.

One writer states that there are two experiments which remain to be tried with Mistletoe—1st, Can it be propagated by inserting cuttings in the live bark in the manner of buds or grafts? 2nd, Whether a plant of Mistletoe would keep alive the tree on which it grows after that tree was prevented from producing either leaves or shoots? The Mistletoe is seldom known to cease growing while the tree is alive, but when the tree dies the Mistletoe dies also. The method of propagating is by the berries, they being made to adhere to the bark of a living tree. The common agency by which this is effected is supposed to be by birds, especially the missel thrush, which after having satisfied itself by eating the berries wipes off such of them as may adhere to the outer part of its beak against the branch of the tree on which it has alighted, and so some of the seeds are thus left sticking to the bark. Aristotle and Pliny among the ancients, and Dr. Walker among the moderns, considered that the Mistletoe was propagated by the excrement of the birds which had fed on the berries, supposing that the heat of the stomach and process of digestion were necessary to prepare the seeds for vegetation. They first suggested the idea of trying by experiment whether the seeds would vegetate without passing through the body of a bird; and at his suggestion Mr. Doody, an apothecary of London, inserted the seed of the Mistletoe into the bark of a White Poplar tree, which grew in his garden, with complete suc-

cess. This, Professor Martin observes, has been since done by many persons, both by rubbing the berries on the smooth bark of various trees and by inserting them in a cleft, or in a small hole bored on purpose, which was the mode adopted by Doody. Mr. Baxter, of the Oxford Botanic Gardens, in the spring of 1833 rubbed nine Mistletoe seeds on the smooth bark of an Apple tree, all of which germinated. Two produced only one radicle each, six produced two radicles each, and one produced three; from which it follows that two radicles are more common than one. In the seeds of the plant there are as many embryos as radicles. The celebrated Du Hamel arguing that the seeds of the Mistletoe like the seeds of other plants would germinate anywhere, provided they had a suitable degree of humidity, made them sprout, not only on the barks of different kinds of living trees, but on dead branches—on bricks, tiles, stones, the ground, &c. But though they germinated in these situations they did not live any time, except on the bark of living trees. M. Du Trochet made seeds of the Mistletoe germinate on the two sides of the frame of a window, and in both cases the radicles directed themselves towards the interior of the room as if in quest of darkness. The first indication of germination is the appearance of one or more radicles. I also learn that Mistletoe can be easily propagated on Thorns, or Crab Apples planted in pots for the convenience of removal. The berries of the Mistletoe, and also of Holly, are used for making birdlime, but differences of opinion exist as to which make the best.

Mistletoe used at one time to be used in England as a remedy for epilepsy, but it is not now used in medicine.

Our Christmas festivities undoubtedly were derived from the heathen nations who used the Mistletoe. The 25th of December was originally their great saturnalia day: hence the early records of revelries and excesses, including the Lord of Misrule and other strange characters.

The Mistletoe, particularly that which grows on the Oak, was held in great veneration by the ancient Britons. At the beginning of their year the Druids went in solemn procession into the forests and raised an altar at the foot of the finest Mistletoe-bearing Oak, on which they inscribed the names of those gods which were considered as the most powerful. After this the principal Druid, clad in a white garment, ascended the tree and cropped the Mistletoe with a consecrated golden knife or pruning hook, the other Druids received it in a sheet of pure white cloth which they held beneath the tree. The Mistletoe was then dipped in water by the chief Druid and distributed among the people as a preservative against witchcraft and diseases. If any part of the plant touched the ground it was considered to be the omen of some dreadful misfortune which was about to fall upon the land. The ceremony was always performed when the moon was six days old, and two white bulls were sacrificed when it was concluded. I may here observe that a gentleman in Penzance, Cornwall, possesses a crescent of gold about the shape of and to represent the moon immediately after she had passed the first quarter. This golden crescent used to be worn by the chief Druid

when cutting the Mistletoe with the golden knife. No profane hand could presume to cut the Mistletoe; nor were all times and seasons proper for the performance of this rite. The legend of Friga and other Saxon deities connected with the Mistletoe is too long for repetition in our pages. The supposed magical properties of the Mistletoe are referred to by many writers. Lelius mentions the Mistletoe as one of the things necessary to make a man a magician or Druid. In the dark ages a similar belief prevailed, and even to very recent days the peasants of Holstein and some other countries call the Mistletoe the "Spectre's Wand," from a supposition that holding a branch of Mistletoe in the hand will not only enable a man to see ghosts, but to force them to speak to him. A writer in the year 1791 stated that the Guibdel or Mistletoe was supposed by some to have been the forbidden tree in the garden of Eden, and adding that hence, probably, arose the custom of kissing under it at Christmas; but it is more probable that the custom has been handed down to us from our Saxon ancestors, who dedicated the plant to their Venus, Friga, the goddess of Love, so as to place it entirely under her control, and prevent it from being used against her as an instrument of mischief. In feudal times the Mistletoe was gathered on Christmas eve with great solemnity, and hung up in the great hall with loud shouts and rejoicing. This has been the theme of many a poem.

"Forth to the woods did merry men go
To gather-in the Mistletoe.
Then opened wide the baron's hall
To vassal, tenant, serf, and all."

From then till now Mistletoe has been considered part of our Christmas adornings.

The most certain mode of increasing the Mistletoe is by affixing the berries to the smooth young bark of Apple or other suitable trees, and a portion of them are tolerably certain to germinate if not devoured by birds. In districts where the Mistletoe is scarce the berries cannot be too thickly sown, and some of them may escape the sharp eyes of the feathered tribe. Failures arise mainly by inserting the seed into crevices of the old bark or not protecting the berries from birds. The plant may be increased by grafting, but not nearly so satisfactorily as by seed. A good plan is to gather the berries at this period and preserve them until the trees are breaking into leaf, and then smear them thickly on the young branches. Some have found it better to raise a flap of bark in the shape of an inverted A, and place one or two seeds beneath it, and thus protect them from the birds.

PEAS NEW AND OLD.

PEAS are the princes of summer vegetables. They have in the garden the best ground and the most favoured situation. On exhibition tables they every year make finer displays and absorb a greater amount of public attention than any other green vegetable. In trade catalogues they are given the post of honour, and in the advertisement columns of the gardening press they have the prominence of which they are worthy. "Peas is Peas all 't' world ower," was the stock phrase of an old-fashioned Yorkshire gardener who prided himself upon being proof against "'t' sorts wi' new names;" but the merits of Veitch's Perfection were more powerful than even the old Yorkshireman's prejudices. That was the first "newsort" that broke down the barriers of his exclusiveness, and he lived to grow other new sorts, and to acknowledge them as being "distinct and good."

It cannot be denied, notwithstanding the force of the old axiom "As like as two Peas," that there is a great dissimilarity in the varieties of this favourite legume. The new sorts are not only distinct in many important features from the old varieties, but they are, except those of the early round section, distinct from each other. The hybrids of Mr. Laxton and Dr. Maclean are totally dissimilar from the "old standards" in character; also, it must be admitted, in price.

Now there are many who resent the "fancy prices" which are attached to new Peas on the ground that they are not worth the money, and that to eat Peas at 5s. per quarter pint is an unjustifiable luxury. True, but the price is not assessed on the table quality of the article, but simply on its scarcity, and if a sort is really new, also distinct and good, it will certainly find purchasers let its price be what it may.

New and high-priced vegetables, and the trade enterprise of vendors by the liberal prizes offered for their new introductions, have been productive of good, not to themselves

alone and to which they are fairly entitled, but as fostering a higher type of kitchen gardening, and making that department of the gardener's duties more enjoyable and attractive. The kitchen gardens of the opulent are not, and should not be, regarded wholly from a utilitarian point of view. They should, of course, primarily be devoted to the culinary requirements of the household, but they also should add a measure of enjoyment, and be a source of interest and pleasure to their owners and attendants. By the introduction of new and proportionally expensive vegetables in small quantities a new and healthy feature is imparted to a garden. The very rarity and cost of the articles will stimulate the gardener to give them the best attention, and by them the garden will become more thoroughly worked and be brought into better condition than before. We may be tolerably certain that those gardeners who make trials in small quantities of new vegetables, and who submit their produce to the great exhibitions, do not fail in the culinary requirements of home, and that the gardens in their keeping are not only not neglected, but that they are in the highest state of culture. This improved state has in a great measure been brought about by the greater value of the crops that have been introduced. In these instances the small extent of ground that has been set aside for experimental purposes has been more than compensated for by the increased productiveness of the rest. Thus nothing has been lost in the utility of such gardens, but to them has been added an element of enjoyment—it may, perhaps, not be unpardonable to say an element of beauty. I am not quite certain that one plant which affords pleasure to the eye and mind is not as beautiful as another. I think I have seen as much beauty in well-cultivated and well-tended trial rows of new Peas as in rows of Roses. Yes, I have turned from the Roses to admire the Peas. So also have other gardeners. I know also garden owners, not only gentlemen but ladies, whose kitchen gardens have afforded them delight; but when devoted solely to purposes of utility they were seldom entered by their owners.

Can anyone suppose that the gardens in charge of such men as Mr. Gilbert, Mr. Lumsden, Mr. Cox, and other gardeners of equal fame, are less productive in useful returns for the new and rare vegetables which are cultivated in them? No: These gardens are in the highest state of culture, their usefulness is as great as ever, and besides being useful they are made infinitely more enjoyable than before, and more instructive.

New and highly-priced vegetables must not, therefore, be judged by their "pot-filling" qualities, but should be regarded as "germs of future usefulness," and in the meantime as objects affording "present pleasures." Just as the stockmasters and lovers of animals and of birds have their highly valued favourites, not as being of real service, but as affording pleasure—hobbies; so may gardens and gardeners have their pets—their "fancy crops"—which add to the pleasure and contentment of the man, and bring out his best qualities, and afford enjoyment, and in the end profit, to the master.

I am probably as practical as most men, and have been as successful in my vegetable supply, yet by the introduction of new vegetables in reasonable quantities I have made my work more pleasurable to myself, and have noticed the increased interest that my employer has taken in his garden by watching the growth of varieties which he has not seen before. The profit of the garden has not been decreased, but its pleasures have been increased. That I hold to be a great gain effected mainly by new and highly-priced seeds of, especially, Peas. They are vegetable "fancies" which have been indulged in with great satisfaction and not without profit. Yet while admitting the usefulness of highly-priced Peas in stimulating the taste in kitchen gardening, I cannot withhold my meed of approval of Mr. Turner for not hurriedly sending out his new Pea Dr. Maclean, but reserving it until his stock has become sufficient to enable him to distribute it in large quantities and at a reasonable price. I do not speak without knowledge of this variety when I say that it is one of the most important acquisitions in new Peas of recent years. Some rows of it were really "beautiful" and exceedingly useful. In cropping and in quality it is alike good. If only a limited number of new Peas can be tried this should be one of them.

I am able also to testify to the merits of some other new Peas, and recommend as eminently worthy of a place in any garden Mr. Laxton's new early variety The Shah. If it does not supersede all early Peas it will at least be worth the crown that it

costs. It should be sown at once for testing with William I., the earliest of the round-seeded section. The Shah is a fine Pea and likely to become popular, unless Mr. Laxton should supersede it, for there appears to be no likelihood that that fertile hybridist will "rest and be thankful." Still finer is its congener which is appropriately named Standard, a designation warranted by its appearance, habit, and productiveness. The above-named varieties constitute a trio which for value and distinctness probably surpass any like number of "novelties" which have been offered in any previous year. They will add to the attractiveness of any garden, and will produce a stock of seed of undoubted value.

I will now notice a few other varieties of great merit which have been introduced during recent years, sorts which I know are productive, and which have been prominent at all important horticultural exhibitions during the past season.

First I name a Pea which has not yet reached its "fullest fame"—Dr. Hogg. This should be sown with the earliest section, and it will form a succession to them, it being almost "a first early," handsome, prolific, and excellent. As a garden and exhibition Pea it possesses high qualities. It should be noted that all exhibition Peas are not high-class table Peas. Thus Superlative and Supreme are imposing in appearance by their size, shape, and colour, yet they are not "high quality" Peas as compared with the best of the wrinkled Marrows. Peas of the Pizetaker strain invariably are better in appearance than quality. The following, however, combine with an imposing appearance superior table qualities:—Fillbasket, Connoisseur, Supplanter, and Omega of Mr. Laxton; G. F. Wilson, James's Prolific, and Commander-in-Chief of Messrs. Carter & Co.; Duke and Duchess of Edinburgh of Messrs. Sutton & Sons. From those named may be selected six of the best exhibition Peas; and as the difficulty is to decide which to exclude, intending competitors must grow them all. James's Prolific is considered by some to be too light in colour for the exhibition table, but on that account it must not be lightly set aside, as it invariably "shows" well, and it is of admitted high quality. Its productiveness is also remarkable, and when had true and well grown its rows are truly kitchen-garden "ornaments," which cannot fail to be admired. It is, I believe, a selection from Wonderful, and indeed it is a wonderful improvement on that useful kind. If the stock is not selected with care it, like other Pea sports, is apt to revert to the normal type.

Most valuable as useful garden Peas and frequently affording pods worthy of exhibition, are Premier and Best of All, which appear to be closely allied, and Veitch's Perfection. Culverwell's Prolific Marrow sent out by Messrs. Veitch must have a place amongst the "most useful" sorts, its high quality, productiveness, and distinct appearance presenting great claims to attention, and which are not likely to be long overlooked. The sorts named may not—indeed they are not, superior in table qualities to some older sorts, but for quality with appearance, for use and ornament, they are those from which a selection must be made.

But there are those who do not require Peas for exhibition. They do not judge of the Peas in the pods, but when shelled and cooked. In a word, they do not want "fancy" Peas, and they will not purchase "new" Peas. Beyond question such can have produce of the very highest quality, for the Pea kingdom has many subjects, and some of the "old inhabitants" possess sterling worth. Take, for instance, Champion of England. If it does belong to the "lower orders" none of the "aristocrats" can better adorn the table. I am not in the "secrets of the seedsmen," but dare almost venture a guess that the public demand for this Pea is greater than for any other "general crop" variety. Whether that be so or not it is a prince among Peas, and if I was compelled to have only one variety that one would be the Champion of England. Huntingdonian and Culverwell's Champion appear to be selections from the Champion, and are undoubtedly good, as they must be, and they may, indeed, be superior in constitution, but for table excellencies they can be no more than equal, and that is high praise. Where ground is scarce and sticks plentiful, and where the one object is a certain supply of superior Peas, that supply cannot be more surely provided than by sowing row after row—from February till May, half of each month inclusive—of Champion of England.

But what before and what after? Well, for before sow anybody's "First Early," that is, anybody having a reputation to lose. If you deal with Carters order "First Crop;" if with Suttons, "Ringleader;" if with Veitch's, "Dillistone's Early."

There will be no difference except on the outside of the parcels. A trifle later, but equally good, is Sangster's No. 1, and better than any but dearer are William I. and Alpha. Any one of these, with a breadth of Champion sown with them in February, will produce "all prizes and no blanks."

But what after that is for latest crops? Here we have many bids for popular favour, and scarcely one that is unworthy of the great Pea family and its patrons who select some special representative. If restricted to one kind I should elect Ne Plus Ultra. I speak after much experience and many trials, and I admit having proved the value of other sorts; but I cannot be separated from my old friend. But it is too tall for many, and then what? Well, then, as the most reliable late Pea of first quality and lowly growth the true Hairs' Dwarf Mammoth has yet no superior. It is not later on first coming into use than Veitch's Perfection, neither is it better, but it is more continuous in bearing, more mildew-resisting, and more hardy, and hence I recommend this good old kind. It may, however, be superseded by Omega, for I know no other dwarf late Pea to which it is for useful qualities likely to yield the palm of supremacy. British Queen, Hay's Mammoth, Tall Green Mammoth, and their many *aliases*, all possess great merit as late Peas, as does General Wyndham, the distinct Emerald Marrow, and other proved sorts; in fact almost all late Peas are good Peas, and few, if any, are likely to disappoint when well cultivated.

I had almost forgotten to mention a "cheap, serviceable, general purpose Pea," the good qualities of which I fear are sometimes overlooked, the best of all Peas, perhaps, for a poor, dry, shallow soil—I mean the old French sort Auvergne. I was glad to see it mentioned in your correspondence columns last week, for if it is very old it is very useful; if I had to feed a school of charity boys I should rely on Auvergne.

Of dwarf Peas the best I am acquainted with are Blue Peter and Bijou; they require deep rich soil to bring out their best qualities.—A GROWER AND EXHIBITOR.

NOTES FROM MY GARDEN, 1875.

I SUPPOSE there are very few persons who can look back on the state of their gardens in the past season with universal satisfaction. We have read complaints from some of our most experienced growers of the losses they met with and the difficulties they had to encounter owing to the wretched character of our summer months, especially that terrible July, when we could indeed say, "The rain it raineth every day." But not less disastrous I think, at least in this part of England, was the drying bitter wind of May and June. Vegetation seemed completely checked; anything that was planted out seemed to diminish instead of increasing; and although great fruitfulness in some things gave us good hopes, yet in many ways we were doomed even in this to be disappointed. I never had, for example, a finer prospect of a Rose bloom, but just at the season of flowering heavy continuous rain gummed many of the flowers together, and destroyed completely the delicate blooms of such kinds as Mons. Noman and Madame Lacharme. For the same cause the Cherry crop in our county was a complete failure: abundant beyond description, but the incessant rain completely spoiled the fruit, splitting and crushing them in threes and fours. And then was there ever such a season for weeds? Not merely was it that they grew luxuriantly, but the ground was so wet that it was impossible to get on it properly, and hence they had it all to themselves. I was almost ashamed to go out into my garden, and quite ashamed to take anybody into it. I am sorry to say I can never lay claim to neatness, and last season it was simply disorder. The finest crop I had in the garden was the Sowthistle, which I consider the most objectionable of all weeds. You may give a pull at a Nettle, or Dock, or Groundsel, and up it comes, but the Sowthistle almost always breaks off, so that you cannot possibly pull it up; and unless you are armed with a trowel or some such implement you must leave it. I know all this is a confession of great weakness, but then it is better to state things as they really are; moreover, I believe many were in the same plight. "I have weeded," said one of our largest growers to me, "my standard Roses three times, and they are as bad as ever." "Weeds! don't talk to me of weeds," said the superintendent of a large garden, "I am sick of them." And as I rambled about I could see, that even where labour was not so great a consideration, that the weeds were masters of the field. Labour is no doubt at the bottom of this. Where it is scarce, as with us, and dear moreover, persons of narrow

means, if they indulge in the luxury of a garden, must, I fear, abandon the hope of having it neat if we have such seasons as the past has been.

My little greenhouse was as full as ever it had been, and went through its usual metamorphosis from the Cyclamen and Camellia season on to the end of the summer, giving me at all times a few flowers—sometimes a good many—and a great deal of pleasure. My Camellias were a great disappointment owing to the dropping of the flower buds. I had in the previous summer, contrary to my usual custom, placed them out of doors; and however this practice may answer where there is provision made for shading and where attention can be given to watering, it is in such cases as mine a mistake, and I find by last week's Journal that so experienced a gardener as Mr. Douglas has come to the conclusion that they are better indoors than out during the summer. I am confirmed in this by the appearance of my few plants at this time (January 10th). They are rapidly opening, and very few if any going brown; and they were simply removed from the greenhouse to my small cool Grape house, where they have been all the summer under the shade of the Vines. I have found too—at least I fancy so—that one or two applications of Standen's manure when they are forming their buds is a capital thing as giving power and vigour to the plants, which are confined in pot room and apparently require something of the kind. I apply it on the surface as powder, leaving the watering to convey its benefit to the soil. There are some sorts more given to dropping their buds than others, and amongst these I have found the old Double White, Fimbriata, and Henri Favre about some of the worst. Of Azaleas I have nothing particular to say. I had no new varieties, and the old sorts, with the exception of Variegata, bloomed well.

Pelargoniums consisted entirely of the new varieties of 1874 and those of 1875 which I had received through the kindness of Mr. Charles Turner. Of course the plants are small. I am obliged to keep them so, and so cannot grow many of the older varieties. Of those which were sent out from Slough last spring the following I especially noted as good:—Archduchess, lower petals richly painted crimson; top petals large spot, crimson-purple edge, white eye. Crown Prince, deep maroon top petals, bright narrow edge, white eye; very fine. Duchess of Cambridge, a very fine scarlet flower, small black spot on top petals; fine form. Duke of Connaught, dark rosy top petals, white centre; a very fine flower. Grand Monarch, dark top petals, crimson edge, crimson lower petals. Presbyter, dark maroon spot on top petals, crimson edge, clear white centre. Constance, a novel flower; fawn colour, small spot, shaded with orange, clear white eye. Alice, maroon top petals, crimson-purple edge, large white eye. I am sorry to say, that after cutting down I have not succeeded with them this year. Whether when put out of doors they had too much rain or not I do not know, but they do not promise well for this year's bloom.

After my Pelargoniums are done blooming I have little left to fill the house. I however mean to try this year, if only for the purpose of cuttings for vases, if I cannot have some Fuchsias. And while writing about decorative purposes let me say that I had in the early part of the season a number of pots of Ixias, and that I found their cut blooms most effective. They are light, graceful, very varied in colour, and last a long time in bloom, while some of the shades of colour, such as viridiflora, are not to be had in any other flower. I have found the best plan of growing them is, after potting them in autumn, to put them into a cold frame and keep them there until the spring, then bringing them into the greenhouse for blooming.

I think it will be seen from these few remarks that my little house of 20 by 10 has done its duty.—D., Deal.

NEW GOLDEN POPLAR.

We have received from Mr. Charles Van Geert of Antwerp a coloured plate representing a shoot and foliage of his new Golden Populus canadensis. It is very beautiful, and those who know Mr. Van Geert are certain that he would not circulate any representation of it which was an exaggeration of the truth. Our forest scenery is destitute of golden tints, except in the autumn, and this new gain of Mr. Van Geert's will add a beauty and variety to it which has hitherto been lacking. In his prospectus Mr. Van Geert says—

"Its leaves are quite as large as those of the common Poplar, and the yellow hue, instead of looking sickly, has a warm and vigorous tint. The better nourished the tree is, and the more

it is exposed to the sun, the more vivid is the golden hue. The stalks and the bark of the shoots become then dark red, which adds greatly to the beauty of the colouring.

"This variety, or rather this freak of nature—for it was spontaneously produced on a single branch of a large tree—has been observed by ourselves for more than five years, and during all this time it has never shown any tendency to alter its golden character.

"This novelty will be ready for sending out in March, 1876, and the finest specimens will be forwarded to the first subscribers."

THE D'ARCY SPICE APPLE.

ABOUT twenty-five years ago an Apple, said to be new, was sent out to the public under the name of Baddow Pippin by the late John Harris of Broomfield, Essex. The scions of this so-called Baddow Pippin from which John Harris obtained his Apple were procured some forty years ago by the late Mr. Jeremiah Pledger of Little Baddow, Essex; it is said from Hazeleigh Hall, Essex; but wherever they came from, they were grafted by a gardener named Robert Rolfe on to a tree in Mr. Pledger's orchard at Little Baddow, Essex. It is from this grafted tree that the late John Harris procured the scions for his Apples which he sent out as Baddow Pippin.

My object in troubling you with this letter is to state that this Baddow Pippin is in reality not a new Apple but the old-fashioned D'Arcy Spice Apple, and has been growing at Tol-

Fig. 7.—D'Arcy Spice Apple.

leshunt D'Arcy, Essex, under the name of D'Arcy Spice Apple for upwards of a hundred years, and I have to ask you to restore to it its true and ancient name. The tree from which I obtained the specimens of D'Arcy Spice Apple forwarded to you is seventy or eighty years old, and is growing in D'Arcy Hall garden; and in the memory of persons still living there were three old worn-out decayed trees of D'Arcy Spice at D'Arcy, which were probably a hundred years old at the time of their decease.

Again. In the year 1800 the then rector (Rev. Charles Carwardine) of Tolleshunt Knights, adjoining parish to D'Arcy, grafted an Apple tree in the rectory garden with a scion of D'Arcy Spice Apple obtained by him from a tree, at that time of some repute, in a cottage garden at Tolleshunt D'Arcy, and then known as D'Arcy Spice Apple.

I think D'Arcy Spice means D'Arcy espèce, and that the same is a very ancient Apple, introduced into this country by the monks who held lands there. D'Arcy Hall is a very ancient moated house approached by a bridge, dated 1575, and is mentioned in Domesday Book. The Apple must not be confounded with Aromatic Buseet, *alias* Burnt Island Spice or Brown Spice.

The D'Arcy Spice Apple is a first-class dessert Apple; the tree does not bear well until of some age, and varies in growth according to the stock on which it is grafted. I think if grafted on a quick-growing stock, or double-grafted, it would become a great favourite. It is a curious fact in the history of this Apple that until last year the D'Arcy people had not the remotest idea that their favourite Apple had been renamed and sold as Baddow Pippin. I do not think that John Harris knew that

the Apple was a native of D'Arcy.—HORATIO PIGGOT, *Broadwater Down, Tunbridge Wells.*

[In Dr. Hogg's "Fruit Manual" Spring Ribston is mentioned as a synonym of this Apple, and it is described as follows—"Fruit medium-sized, roundish or rather oblate, with prominent ribs on the sides, which terminate in four and sometimes five considerable ridges at the crown, very much in the character of the London Pippin. It is sometimes of an ovate shape, caused by the stalk being prominent instead of depressed, in which case the ribs on the sides and ridges round the eye are less apparent. Skin deep lively green, changing as it ripens to yellowish green on the shaded side, but covered on the side next the sun with dull red, which changes to orange where it blends with the yellow ground; the whole considerably marked with thin brown russet and russety dots. Eye rather large and open, with short segments, and set in an angular basin. Stalk very short, not more than a quarter of an inch long, and inserted in a shallow cavity. Flesh greenish white, firm, crisp, juicy, sugary, and with a particularly rich and vinous flavour, partaking somewhat of the Nonpareil and Ribston, but particularly the latter. This is a first-rate dessert Apple; in use in November, and possessing the desirable property of keeping till April or May."]

IRIS RETICULATA CULTURE.

IRIS RETICULATA is a hardy plant, but requires, to grow it well, a warm corner and a bed of pure light sandy loam; in the ordinary soil of an old flower garden the bulbs are apt to rot. This and many other small hardy bulbs will generally break up into offsets and dwindle under pot cultivation. The commonest Crocus or Tulip will do the same. Grow the Iris as I have described; take up and store in dry earth or sand when the foliage dies down, and select the best bulbs to flower in the greenhouse; in the autumn restore the bulbs to their old quarters. They will come round again after one season's growth. The Peacock Iris should be grown in the same way, but absolutely requires a glass frame over the bed.

Pot culture is, however, possible for such plants, and I recommend the following treatment: Use rather large pots—say 8 inches across; soil, very sandy pure loam; drainage, one or two large crocks with a good large handful of moss over them. Put in plenty of bulbs—say 2 inches apart, grow them in a good cold frame through the winter, and bring them into the greenhouse in the spring to flower. If you are short of Pavonias fill up the space with Tritonias as an edging round the pots.

To Mr. Robson in the matter of Cyclamens; my old friend Mr. Atkins of Painswick knows more about them than all of us put together, and would doubtless give the required information. *C. persicum* has many local forms, and runs riot in variation even in the wild state. *Coum*, *repandum*, *euro-pæum*, and *hederifolium*, with, perhaps, *ibericum*, are true species.—R. TREVOR CLARKE.

GROS COLMAN GRAPE.

I HAVE under my charge two rods of Gros Colman growing in a Muscat house, both worked, the one on the Black Hamburgh, the other on Muscat Hamburgh. I am glad to be able to differ from "EX-EXHIBITOR," for with me it is a first-class late Grape, not only a noble-looking fruit, but of good colour and flavour, and so much approved of by my employer that I am working another on to the Muscat Hamburgh. Not only is this Grape good planted out, but I accidentally discovered that it makes a good pot Vine. I forced one with some Black Hamburgs, and it produced three bunches averaging about three-quarters of a pound each, well coloured and of good flavour, and which ripened in about a fortnight after the Black Hamburgs. I have another cane up one of the rafters in the Peach house where fire is not used after the fruit is set; that also produces noble bunches and berries which colour well, but the flavour is not good.

I certainly should not recommend anyone to plant Gros Colman in a cool house, but where it can have the advantage of a Muscat temperature I consider it one of the best late Grapes we have. I may state that my Vines are all planted inside and not allowed to go outside at all.—S. TAYLOR, *Castlecroft.*

I HAVE found this to be the best variety of late Grape grown, and a most wonderful bearer. It must be kept late to bring

out the proper flavour. I cannot boast of such large bunches as Mr. Turton speaks of in your last issue, as ours is not a soil suited to grow heavy bunches; but still they are wonderfully large.—F. W.

ROLLESTON HALL.—No. 2.

THE SEAT OF SIR TONMAN MOSLEY, BART.

VERY incomplete would a notice of the gardens at Rolleston be if limited to their ornamental features. These were fully alluded to in our No. 768. In continuation from those pages I now proceed to notice the more useful department of the gardens.

The glass structures are numerous, some old, some new, and they are scattered over a considerable extent of space, a consequence of being erected at various periods, and in consonance with the improvements which have been made by Sir Tonman, and his predecessor, Sir Oswald Mosley. These structures number twenty-four exclusive of frames, and, excluding the conservatory, contain nearly 20,000 superficial feet of glass. They are heated by 11,000 feet of 4-inch piping attached to two boilers, one heating 8000 feet and the other 3000.

The heating has just been remodelled under Mr. Buck's supervision with very successful results. The boilers, with their outlets and inlets, and the piping connection contiguous, are in every part accessible by removing a portion of the flooring of flagstones, which form the roof of the heating chamber below. There is no setting in brickwork, but every part of the arrangement can be examined, which is an admirable provision facilitating after-repairs and, if necessary, further alterations. The smoke is conducted away to a tall shaft at some distance from the houses. This has been an extensive and costly work, but Sir Tonman is evidently a believer in the old sayings "what is worth doing at all is worth doing well," and "what is well done is twice done;" that he recognises these truths the observer finds abundant evidence.

I will now, as briefly as possible, notice the contents of some of the houses. The old range of vineries is entered by a corridor leading to the museum. The roof of this corridor is covered with *Maréchal Niel* Roses and *Bignonia*s trained after the manner of Vines, and which yield a valuable supply of cut blooms; the compartment is further kept gay with pot plants in variety. The first vinery entered is a Black Hamburgh house 30 feet in length, the Vines being old and trained on the extension system. The next house is also a vinery of the same size, and is mainly occupied by the Vine that almost fills the preceding house, only in one compartment it is the Black Hamburgh while in the other it, by grafting, yields in addition fruit of *Trebbiano* and *Lady Downe's*; and further, in one division the fruit is ripe six weeks earlier than in the other, all alike good, being well coloured and flavoured and free from shanking. Without saying that the extension system produces the best Grapes it may almost be asserted that it is the easiest and simplest mode of producing them, and that none need hesitate on treating Vines thus naturally, especially if they have not been satisfactory on the more artistic (artificial) plan of restricting them to single rods.

The next is a Muscat house 50 feet in length. The Vines have been planted five years, and are in admirable condition; they are planted inside, the roots having access to outside borders. Adjoining is a house of a similar size planted with Black Hamburgs, *Alicantes*, and a Vine of *Gros Guillaume*. The Vines are young and produce excellent crops; as an instance of their vigour it may be noted that this season's cane of *Gros Guillaume* is upwards of 4 inches in circumference. The Vines are planted 4½ feet apart, and the houses are staged for plants.

We now enter a new range of glass, the first house, which is 40 feet long, being devoted to *Azaleas*. The plants are remarkably healthy, and many of them are large and very handsome, some of the best plants having been purchased from *Osmaston Manor*. The back wall of this house is covered with *Lapageria rosea*, and the white variety is growing on the roof. Mr. Buck finds that *Lapagerias* flourish best on a north aspect.

We now enter the early Peach house; it is 50 feet in length, and planted principally with *Royal George* and *Bellegarde* Peaches and *Violette Hâtive* Nectarines. It is a fine light house, the border being wholly inside, and the trees are started in November. In this house were also starting into growth standard Oranges on 6-foot stems, having compact heads; they are in pots and will shortly adorn the conservatory. Adjoining is a

mixed vinery filled with fruitful Vines, and the next house is the late vinery, 80 feet in length. The roots are confined to the inside border, which is only 9 feet wide; but, clearly, sufficient, for a larger and finer crop of Grapes has seldom been produced. Black Alicante is in its best style, and the berries of Gros Guillaume on the Black Hamburgh stock are as black as jet. Lady Downe's is represented by fine bunches and splendid berries. Madresfield Court has shrivelled, but no Grape is richer; it is a valuable variety, but not to be relied on for late keeping. Mrs. Pince is not quite satisfactory; the crop is heavy, bunches fine, berries large, and flavour good, but not one bunch is nearly well coloured. It is grown on its own roots and is also grafted on the Lady Downe's and Black Hamburgh stocks. On its own roots it is the best flavoured, on Lady Downe's the largest, and on Black Hamburgh the sweetest; but on all the fruit is brown—a great drawback to an otherwise good Grape. Trebbiano and White Nice are represented by heavy crops of fine clean fruit, and on the last-named stock is a vigorous cane of Duke of Buccleuch. The back wall of this grand house of Grapes is covered with Black Hamburgh Vines, which afford useful fruit for kitchen purposes. This heavy crop of Grapes has been perfected by copious waterings and rich top-dressings. Mr. Buck has never before given the border so much water and never had the crop so fine. He ceased watering when the fruit commenced ripening, and the top-dressing prevents evaporation and preserves a dry atmosphere. The Grapes were ripe at the end of September, and the crop is best at the warm end of the house. The most useful kinds for late keeping are Lady Downe's and Black Alicante.

Contiguous to the range just noticed is the orchard house. This very fine span-roofed structure was erected by Mr. Foster of Beeston; it is 74 feet long by 30 feet wide. The house contains a narrow border all round, with two central borders each 6 feet wide, the central path being between these, and there is also a path between them and the outside borders—that is, three paths and four borders. The central borders are principally occupied by standard Peach and Nectarine trees, and planted out in firm soil. The heads of these trees are large and open, and are studded with spurs to their centres, each tree perfecting eight to ten dozen of fruit. The borders are not dug, and the roots are pruned biennially. The remaining space is occupied with pot trees of Peaches, Plums, Cherries, and Apples, the trees being in a high state of fruitfulness and in exuberant health. The soil used is turfy loam and crushed bones, supplemented with surface-dressings of horse droppings and kiln dust. Vines are trained up the pillars, and are arched across the paths at wide intervals; they yield superior Grapes, and do no injury to the trees beneath. The house is now heated, and the heating has greatly improved its value, the crop being now certain, however dull may be the autumn or inclement the spring. It is a fine house admirably managed.

Entering the walled kitchen garden we find still more glass, plant houses, pineries, and Peach case. The plant houses, three in number, were erected by Mr. Ormson as "feeders" to the conservatory. Each house is 30 feet in length by 15 feet in width, lofty, and with central and side stages. The central house is heated for stove plants, the others being kept at greenhouse temperature. In the latter are healthy collections of Heaths, Camellias, Rhododendrons, Plumbago capensis on globes, very fine; Primulas, Cinerarias, &c. On the roof of one house is trained *Passiflora edulis*, heavily fruited, but the temperature is insufficient to ripen the crop. The roof of the stove is covered with Allamandas, Bougainvilleas, and Clerodendrons, which flower profusely and afford shade to the Ferns and Orchids. In this house are many Palms, comprising Kentias, Geonomas, Coccos Weddelliana, and other choice kinds; and in brilliant garb is *Aphelandra Roezliana*. The house is further gay with Poinsettias, Eucharisses, and Euphorbias.

There is yet another low range of span-roofed pits, one being devoted to Ferns, another to Nepenthes, Orchids, and table plants, the roof being covered with *Stephanotis*, and others to Pines.

The pineries consist of two succession pits 40 feet long, and a larger fruiting house. These pits are sunk below the ground level—heat economisers—the roofs only being exposed. The Pines are not grown at a high temperature, and the plants are in superb condition, some of the Smooth Cayennes of fifteen months old having fruits of from 5 to 8 lbs. weight. Queens and Black Jamaicas are also grown. The visitor to Rolleston

is sure to want a second look at the Pines, for they are unusually healthy and fine. At the back of this range is a narrow propagating house 80 feet in length, heated by the mains which supply heat to the pineries, or, in other words, heated for almost nothing, for instead of encasing the pipes with sawdust they are covered with glass, a sunk path affording access to this most useful pit.

On the south wall of this garden is a Peach case 130 feet long by 8 feet wide. Along the front is a row of espaliers 8 to 4 feet high, and the back wall is covered with healthy young trees. The trees are thinly trained, and consist of all the best sorts, and yield a great supply of valuable fruit.

The kitchen garden is five to six acres in extent, and is heavily cropped, the Raspberry quarter being particularly neat, and it certainly must be productive. The canes are trained to wires 5 feet high, the rows being that distance apart. Strawberries are largely grown, the staple sorts being President and Keena's Seedling, two thousand of which are annually prepared for forcing.

In the frame ground is a pot vinery 30 feet long. The Vines are started in November, the pots being plunged in tan, and the canes trained round sticks to induce the buds to break regularly. There is also a Cucumber house of the same length, containing hundreds of Poinsettias and Eucharisses; a Camellia house 45 feet long, and 2000 superficial feet of pits for the forcing of Potatoes, Asparagus, &c. Such is a rapid glance of the gardens at Rolleston. The demands of the establishment are considerable, but it will be seen that Sir Tonman has afforded adequate means that the supply can be produced to his own satisfaction and with credit to his gardener.

The root-stores and fruit-room just erected by Mr. Buck demand notice by their size and completeness. The fruit-room is 50 feet in length by 30 feet wide, and 10 feet high. The walls are hollow, having 3-inch cavities; the roof is hipped, and lined with dry sawdust, and the floor is cemented. Thus the building, being over a cellar, is rat-proof, frost-proof, and damp-proof. It is surrounded by three rows of shelves for the fruit, with a rack at the top of them for bottled Grapes. A central tier of shelves will occupy the body of the building. These, with the roof, are well made of smoothly planed deal, the whole of the woodwork being stained and varnished. A simple and efficient system of ventilation is provided by slides in the roof. This is a model fruit-room, its size, construction, arrangement, and high finish of the workmanship being all noteworthy.

Beneath are the root-stores. The centre is occupied with a pit 8 feet wide and 3½ feet deep, with walls of 9-inch brickwork. This is surrounded by a path 2 feet 6 inches wide, and next the walls all round are a series of bins 3 feet wide built of single bricks, some of the smaller compartments being lined with cement for preserving nuts. Over the bins are tiers of shelves for the thin storing of seed Potatoes. For roots of all descriptions and in almost any quantity, for the gentle forcing of Rhubarb and Seakale, and for Mushrooms in summer, this cellar is admirably adapted, and is a valuable appendage to the garden. It is entered by a sunken door near the end, and at the other end is a slanting "shoot" for pouring in the roots. At the back of the building is the garden stable, and cart shed. In addition to this there is a spacious and well-heated Mushroom house with stone bins.

Sir Tonman has also recently erected convenient and sufficient rooms for the under gardeners, the foreman having separate apartments, and every necessary attention for their comfort is provided.

Another striking feature of Rolleston is the museum. It adjoins the block of buildings last noticed, and is entered from one of the vineries. There are not many readers even of "this end" of the Journal but who would enjoy an inspection of this rich museum, while those of the "other end" would revel amongst the thousands of birds familiar and rare, home and foreign, which are arranged and classified in beautiful order. Altogether the gardens of Rolleston are instructive. That they are well managed can hardly be otherwise when we remember the experience and antecedents of Mr. Buck, who was trained at Hawkesyard Park and Keele Hall, and has held his present charge for sixteen years. His father was gardener to T. R. Hall, Esq., of Hollybush, for thirty-four years; his grandfather was gardener to Lord Middleton, and his great grandfather was gardener to the Emperor of Russia. I have to thank him and Mrs. Buck for their attention, and especially to acknowledge the hospitality of Sir Tonman Moaley. Rolles-

ton is two miles from Tutbury station, and four miles from Burton-on-Trent.—J. W.

NOTES AND GLEANINGS.

THE ANNUAL MEETING OF THE HORTICULTURAL CLUB was held at the club house, 8, Adelphi Terrace, when the accounts were audited, and were very satisfactory. Dr. Henry Bennet of Weybridge and Mentone, Capt. Christy of Buckhurst Lodge, Sevenoaks, and Dr. Denny of Stoke Newington, were elected members of Committee in lieu of three members who retire. It was determined that during the winter months occasional meetings for discussion on subjects connected with horticulture should be held; the first being on the 19th, when the subject will be the principles and practice of pruning. Messrs. Maurice Young, John Waterer, and George Christy have been elected members. The formation of a library was determined upon, and the Committee will thankfully receive any works on horticultural subjects which may be given for that purpose.

A few friends of Mr. ALEXANDER MCKENZIE, as a tribute of their appreciation of him, have resolved, on the occasion of his relinquishing his active duties at the Alexandra Park (although still occupying the position of Consulting Landscape Gardener to the Company), to present him with a suitable TESTIMONIAL as a memento of his long and valued connection with the neighbourhood, the various public works he has executed, such as the laying-out of the Alexandra Park, the Thames Embankment, Finsbury Park, &c. Mr. John Bertram, Alexandra Palace, Muswell Hill, N., is Honorary Secretary to the Committee.

Messrs. DICK RADCLIFFE & Co. have prepared, to place over the hole in flower-pots, a square piece of zinc having a number of holes punched in it, one side having a jagged edge, and this is placed downwards in the pot. While preventing the ingress of worms it does not prevent their egress, and at the same time it forms a capital drainer of itself.

WILBERFORCE'S GARDEN.—The only remaining portion of the well-known garden at Kensington Gore in which Wilberforce and his sons were wont to disport themselves was sold last week by Her Majesty's Commissioners for the enormous sum of £108,000. The plot has a frontage of about 50 yards to the Knightsbridge Road, and a depth of about 80 facing the east side of the Albert Hall. It has been bought with a view to the erection of a few first-class houses, the price per yard being something like £25, whereas in Wilberforce's time it might have been difficult to get as many pence. One of the Mulberry trees mentioned in his "Life" as the scene of many a pleasant romp with his children may still be seen standing, but we fear it has not many months, perhaps not many days, to live.—(The Rock.)

We are informed that an article will appear in the forthcoming "St. James's Magazine" on the HISTORY OF THE ROYAL HORTICULTURAL SOCIETY by Mr. Lindsay, late Secretary to the Society. From the opportunities Mr. Lindsay had of access to the records of the Society we have no doubt but that his treatment of the subject will be at once interesting and instructive.

On the 22nd of December last a MONUMENT was erected in Père-la-Chaise, Paris, to the memory of M. BARILLET-DESCHAMPS, formerly head gardener to the City of Paris, a gentleman well known to horticulturists throughout the world. The memorial consists of a base surmounted by a large stone sarcophagus ornamented with drapery, flowers, and other appropriate emblems, the whole crowned by a bust of M. Barillet. An address was delivered by M. Henry Vilmorin, in which in choice language he reviewed the principal works of the deceased, and he was followed by M. Ermens and M. Felix Lepère, fils.

KEEPING GRAPES LATE.

I AM afraid there will be many young gardeners who, like myself, have read the very able and interesting articles on Grape-growing and Vine borders, who will conclude that it is almost an impossibility to have good late Grapes when the borders are outside and with no covering of any description to keep off rain. But that good late Grapes can be had under the conditions I have named, and a good stock of bedding plants kept in the house as well, I will endeavour to prove.

In my late vinery there are planted six Black Hamburgs and one Alicante. The Grapes were ripened the latter part of

September by the aid of a little fire heat, which was kept up during the month of October to thoroughly ripen the wood, but afterwards only in damp weather; ventilation being given at the back.

A fine bright morning is taken advantage of to water the plants. When the pots have finished draining the house is mopped quite dry, the hot water turned on in the pipes, and the ventilators let down a considerable distance, so that by night the house is quite dry.

I must add the pipes were painted with sulphur in the autumn, which has been allowed to remain on all the winter. We have been troubled very little with mildew, and have between forty and fifty bunches of Grapes at the present time—Hamburg and Alicante—most of them looking as fresh as they were in September.—W. E.

NEW BOOK.

The Dwellers in our Gardens, their Lives and Works. By SARA WOOD. London: Groombridge & Sons.

THERE are many dwellers in our gardens besides plants and flowers, but how few of us there are who take heed of them. Plants for use and for ornament are the objects which most receive the gardener's care and attention; but the birds that cheer him with their song and fill his groves and pleasure grounds with melody, the insects which aid him so much in securing him crops of luscious fruit, and the reptiles even which are frequently so much despised, how little heed do they too frequently receive! The work before us draws attention to all these dwellers in our gardens, and makes us familiar with their natures, their haunts, and their habits. As an illustration we extract the following on the ant—

"In each ant city there are three kinds of inhabitants, and on all three kinds the good of the whole community depends. There is no such thing as an ant living or working for itself, providing for its own wants or those of its young, as with most other creatures. All ants live and work together for the benefit of the whole population in each community. In each of the latter there are males, females, and working ants. The males and females have to produce the young, and so supply inhabitants for the city, while the working ants have to work for, and feed, and take care of the males and females and young, and construct the cave-cities, and it is these indefatigable little creatures with which we are best acquainted from seeing them above ground when they come up on matters of business. On them depends, in fact, the well-being and lives of all. It is they, as we have shown, who are so busy when the fine weather sets in in hollowing-out the caves or cells, which will be wanted for future progeny, and which they connect together with galleries and passages, so that all are communicable one with another. Some of the caves are for the reception of the females who are to become the mothers of a future generation, others are for the males, and others are destined for the eggs which produce the grubs or larvae, and others for the cocoons from which the perfect ants are to be hatched. The female ants being much larger than either the males or workers, larger cells are wanted for them of an oval form suited to the shape of their bodies, and where they are waited upon and tended with great care and respect, since on them depends the keeping-up of the population, which seems to be the great aim of all ant labour and industry; and when we consider how a constant diminution of their numbers must be going on from the fact that many species of birds make them their food, we can understand how necessary this strong instinct is in the nature of the little creatures, if the ant race is not to die out and become extinct. The greatest care, and exactness, and skill is shown in the formation of the little cave cells. The walls of them are built-up of grains of earth fitted into each other with great precision, and then it would seem they are covered over with some kind of cement which the creature has the power of secreting from its body, and when the whole is done the small mason will carefully pass his feelers over his work to see that all is smooth, compact, and firm, just as a human mason will measure his work with his rule to satisfy himself that his bricks are all level, and his wall upright.

"During the winter ants spend their time in a torpid state in their underground caves, and at this time the hive is filled perhaps only with workers, and the cocoons ready for hatching when warm weather comes, and it is to prepare for the fresh populations that new works and additions to their cities are made in spring, and when these are once finished the whole character and employment of the working ant undergoes a complete change. The same anxiety for the good of the whole community, the same devotion to the interests of their race and city show themselves, and the same self-denial and unwearying industry goes on; but they are now no longer miners or masons,

no longer 'navvies,' but become most tender and careful 'nurses.' From the time that the city is supplied with new abodes, and that the warmth of the sun is felt even beneath the earth, the wonderful transformation begins within the ant-cocoon which is to change its contents into a living creature. Just when the mother bird is sitting on her eggs in her snug nest, so as to give the warmth needed for their change into young birds, the ant nurses begin their loving attentions to the cocoons in their caves, which also require heat for their change into living ants. More eager bustling begins among them, which we cannot always see, since it goes on beneath ground. When the sun shines out bright and warm, the cocoons in the cells deep down below in the hive must be carried-up to nearer the surface, where the warmth will reach them, and to effect this the whole army of nurses is in commotion; and if we can manage to catch sight of them at such times we shall see each little worker with a white oblong cocoon—not very unlike a baby in swaddling clothes—held by the end in her jaws or mandibles which she carries before her, and which forms a load almost as large as her own body, or even larger if it be the cocoon of a future male or female. But the cocoons have, perhaps, not long been placed in the warmer cells, or laid in some passage or gallery near the opening of a shaft, when the sun becomes obscured and a shower begins to fall. Now although the white covering of the cocoons is a tolerably tough and strong material, yet it would not do for them to be exposed to both cold and damp, and the careful nurses have to set to work to carry their charges all back to the lowermost cells where the rain will not reach them—to bring them up again, it may be, before the day is over, in case the sun should re-appear. No end is there, in fact, to the tender care and indefatigable attention of the nurses. It has been no doubt this running about with the white cocoons in their mandibles, or the finding of them in their nests in the winter, which has led to the mistake of supposing that ants stored-up grains of corn and other seeds, which is certainly not the case with any ants known in England, who pass the winter in a dormant state. Naturalists have, however, lately become aware that a peculiar species of ant found in some other countries does lay-up a store of food such as corn and rice, and have named them 'harvesting ants.' It may have been of such that King Solomon speaks, who was so knowing about plants and animals, where in his proverb he describes the ant as 'providing her meat in summer and getting her food in the harvest;' while in another way his knowledge was also most correct, since he speaks of the ant as 'having no guide, overseer, or ruler,' for it is certain that all the operations of the working ant, all her busy industry and anxiety for the good of the community to which she belongs, arises from an impulse within the little creature forming part of her nature, which is very like the love of duty in a human being. It does not surprise us to find other animals taking tender care of their young, and we admire the devotion and self-denial which they often show towards them, but with the ant-nurses it is the young of others whom they tend, and the good of the whole of their fellow citizens which is the aim of their labour. They seem to have the feeling which we call love of our country, or national honour and pride. They are not slaves by any means, for no one orders or exercises authority over them—they are rather willing and devoted servants to the general good. The powers, feelings, and affections of ants being so many and so curious, it has been said that the brain of the ant, perhaps no larger than a fine grain of sand, must be the most wonderful particle of matter in the world.

"But though our ants do not store-up food nor eat in the winter, they have at other times good appetites, and within our garden walls an abundant supply of food is found, suited to the taste and fitted for the nourishment of the ant colonies. They like most kinds of fruits, sweet roots, and even the flesh of slugs and snails. A dead mouse or sparrow is soon attacked and their bones picked clean by hungry ants. We know too well how a fallen Pear or Apple is often found to be hollowed-out by ants, and how our Peaches and Nectarines are attacked by them and riddled with holes. Nothing in fact that is sweet comes amiss to them, and portions of food are at all times carried down by the workers to the grubs or larvae hatched from the eggs, or to the young ants which have just left the cocoons. Their strong jaws or mandibles enable them to bite solid food and carry it in their mouths, while they have also a kind of hollow tongue like a scoop which can be used for lapping-up liquids, and is perhaps employed for taking home some of the sweet juices of fruit. We know how wonderful is sometimes the persistent industry and determination of the little creatures in getting at the kinds of food they like best. To an ant-city at one side of our garden, for instance, there is carried somehow in August the perfume of the ripening Peaches on the wall at the opposite side. We cannot detect the fragrant

odour so far off ourselves, but the sensitive nerves of the tiny ants must discover it in the air. It may, to be sure, be possible that some adventurous ant traveller has penetrated across the vast (to them) extent of land which stretches between their hive and the wall where hang the downy Peaches that are getting softer and sweeter every day, and that he has journeyed back to tell his fellow citizens what he has discovered, and has induced a large party to set off and make a causeway across the paths and beds, and form tunnels under the turf borders to where the Peaches can be reached by climbing the wall. We can easily see that a long procession of them is constantly doing this, though we know not exactly how they have first been induced to undertake such a distant exploration. But there can be no doubt that ants have wonderful ways of communicating with each other, nor that they have something like a language of their own. If we watch a party going to and fro across a path, we soon observe that they occasionally stop as they pass each other, touch one another with their feelers or antennae, and then continue their route, much as we do ourselves when we meet a friend and have a chat with him in the street. Naturalists who have observed the ways of ants very carefully and constantly have seen that when any calamity has occurred in the colony, the workers will run about and tell the news to those at a distance with a touch of their feelers, and that then all who are so warned will hurry to the scene of the disaster in order to set about repairing it. Perhaps even sounds are emitted by ants, and many other insects, which are too fine and high-pitched for our ears to hear, as the elephant who hears the deep notes of an organ or drum cannot hear the high and shrill notes of a pipe or flute. There have been cases where ants seem to have got scent of some store of honey, or treacle, or sweet preserve within a house, and have journeyed a long distance in great numbers to reach it, even making their way down chimneys to get to the luscious store, but our garden ants are generally contented with what they can find without doors."

This charming book is beautifully and liberally illustrated with coloured plates and numerous woodcuts remarkably well executed, and we can recommend it as a very useful, instructive, and entertaining companion to everybody who has a garden; but O! Mrs. Wood, where is the index?

HOOPER & CO'S TRELLISES.

We have seen some of these new plant trellises, and Messrs. Hooper are quite justified in saying that they are unique in appearance, elegant in finish, and light. They have the advantage over other trellises that they are without sharp angles,

Fig. 8.

Fig. 9.

so that the training of plants gracefully is facilitated. Fig. 8 is for any plant requiring training. Fig. 9 is specially adapted for Ivy and other plants of similar habit.

OUR BORDER FLOWERS—NIGHTSHADES.

I THINK it would be difficult to find a more beautiful family of plants than the Nightshades, especially that section now under notice. For decorative purposes, for pot culture, also for beds, borders, or rockwork, the Nierembergias are admirably adapted. They are said by some to be hardy, but in the localities where I have cultivated them I have had to treat *Nierembergia gracilis* as half-hardy, yet it is easily preserved through the winter in any cool and moderately dry structure from which frost is excluded. Cuttings root freely in well-drained pots and very sandy soil. If inserted in the summer and autumn and placed in a cold pit they may be potted-off in spring, and grown-on in pots, or they may be planted where required. This is a charming plant for edgings, vases, or baskets; it is appreciated wherever it is met with on account of its graceful habit and lovely flowers.

N. calycina is a neat and attractive plant, but is not nearly so well known nor so freely cultivated as it ought to

* We may say here, since it has been discovered that the working ants are really females, though imperfectly formed ones, so that they do not produce eggs.

be. *N. frutescens*, too, is an acquisition that ought not to be passed by; it is of much taller growth than the preceding, of good habit, and may be turned to good account where border flowers are cared for. It ought to be in all collections. *N. Veitchii* is a very desirable plant, of dwarf habit, and is well adapted for a place in very choice selections of rock plants. But I claim the palm for *N. rivularis*, which is quite hardy. In my estimation this is one of the choicest hardy herbaceous plants that we possess. When well established in a nice moist situation on a rockery or border, its beautiful flowers cannot fail to be admired. This species is of recent introduction, and is worthy of being included in all collections of border flowers. It may be increased by division, cuttings, and seed.

Sandy loam and peat with well-decomposed vegetable matter well mixed together will grow all the *Nierembergias* well.—
VERITAS.

EUPHORBIA OFFICINARUM.

We have been appealed to to give the specific name of a "prickly fleshy Cactus." The plant is not a Cactus at all, but

Fig. 10.—*Euphorbia officinarum*.

the mistake of our correspondent is pardonable, for the resemblance of this *Euphorbia* to a Cactus is sufficient to mislead the ordinary observer. We have only to glance at the

species now figured and the well-known and popular stove plant *Euphorbia jacquiniiflora* (*fulgens*) to appreciate the extreme dissimilarity of the different members of this great family—so great as to number upwards of 2500 species. The example figured is a stove plant, and was introduced from Africa nearly three centuries ago, but it will grow well in vinerias if the plant is kept dry during the winter and has the soil and treatment usually afforded to Cactuses. It is only in old gardens that plants are found, and where they have been permitted to exist as "belonging to the place;" but now curious succulent plants are more cared for than they have been during recent years, and are again thought worthy of cultural attention.

The *Euphorbias* possess great medicinal properties, and, according to Endlicher, *Euphorbia officinarum* is the plant that King Juba discovered in Barbary, and named after his physician, who was brother to Musa. It is a native of Africa, Arabia, and India, and is one of those Cactus-looking species, without leaves, with erect, thick, fleshy stem and branches, having the appearance of candelabra; each branch is terminated by a red flower, and is covered with knobs, from which issue sharp spines. This is the species supposed to yield euphorbium, although *E. canariensis* and *E. antiquorum* have also been given as its sources. This is obtained by making incisions in the plant, from which flows an abundance of acrid milky juice that concretes on exposure to the air. Bruce states that he met with it in Abyssinia, where it is called Kolquall, and says that when the branches become old and withered, instead of milk they contain a powder so acrid and piquant that it causes sneezing by merely shaking them; this powder is euphorbium.

OLD TREES.

MISTAKES, when faithfully chronicled, afford great instruction. It is not too much to say that by remembering my own errors and observing the errors of others that I have derived more substantial information than has been afforded by successes. Failures, with the loss and inconvenience resulting therefrom, are more firmly impressed on the memory than are successes, for an accident or a narrow escape from serious injury is remembered for a lifetime. There are few, especially gardeners, who in a long period of practice have not committed many and serious mistakes, and which now stand out as danger signals.

A man who can boast that he never made a mistake is not likely to have made many experiments, or to have risen above the degree of mediocrity. Yet how seldom we see mistakes acknowledged, as if the admission of them was derogatory to a man's dignity, forgetting that by ignoring them the most valuable of life's lessons are lost, and that by admitting them a manly act is done and a great service rendered to those who are ever liable to similar errors.

Our genial mentor, "WILTSHIRE RECTOR," has in his "greetings" grappled with the subject of fruits, and has assailed my conservatism of "old trees." The rector speaks of the trees as moss-covered, scrubby, cankered, ugly, &c., and desires their removal and replacement by pyramids in poor men's gardens. Our friend's remarks are theoretically sound, and are prompted by the best motives; but I can bring some hard practice to bear on the matter which "WILTSHIRE RECTOR" has not experienced. In order to do this I am tempted to fall into the autobiographical groove.

I was born under a poor man's roof, and can well remember when a family of nine had to subsist on the "breadwinner's" earnings of 10s. a-week. Before the cottage grew two old Apple trees gaunt, scraggy, and ugly, but—they paid the rent. In due time I became a gardener, and at the mature age of twenty-two was promoted from foreman in "my lord's" garden to chief in the "squire's." Of course I knew a great deal (more than I do now), and my father was persuaded to let me "improve" his garden by uprooting one of the old monarchs, grafting the other, and planting as compensation a dozen pyramids in (of course, as I was young then) as many different sorts. I further stipulated to pay the rent until the young trees came "into profit." Sequel.—I had to pay that rent for ten years, or just £40. Had the young trees been all of one sort, as Lord Suffield, Beauty of Kent, Dumelow's Seedling, Cox's Orange Pippin, or any other free-bearing kind, I should, no doubt, have saved fully £20; but the sorts coming in one after the other—a dozen of this and a peck of that, brought no useful and substantial return to compensate for

the fifty to sixty pecks which were commonly yielded by the old trees. Further, when the fruit again paid the rent the greater portion was produced by the old tree that had been cut down and grafted. The scions did not grow, but the old stump put forth vigorous shoots, which are now fruitful branches, and I cannot predict how long it will continue to yield valuable fruit.

Many a gnarled old orchard tree may invite uprooting; it is moss-covered, and apparently exhausted, but the real fact is its energies are crippled and its channels of life obstructed; remove the obstruction, and note its liberated power. It puts forth new leaves, new branches, new roots, and new fruit. If the trunk of a tree is healthy and the kind is good, yet the produce still trashy, cut it down and do not graft, and in the poor man's garden the old tree will be more profitable than the young pyramid. If the kind is not good, of course graft. Either plan is preferable to uprooting—that is, if the old stem is healthy.

The dozen pyramids which I planted twenty years ago are now fruitful trees, but have long ceased to be pyramids. They have gone the way such trees usually go under such circumstances, the only pruning they receive being the gradual removal of the lower branches until the trees become useful standards, needing (which in such places they cannot receive) no summer-pinching, but forming natural spurs on natural trees. Pyramids, where they can have skilled attention, are both profitable and attractive, but I cannot resist recommending old-fashioned standards as the trees to fill the markets with useful fruit, and pay the poor man's rent: hence it is that I plead for "old trees," and enter my protest against their hasty and wholesale destruction. Renovate, I urge emphatically, but do not destroy.

I once committed an error on a larger scale. The orchard in my new echange was an old one; the trees were mossy, scraggy, and ugly. As is common, between the young man and old trees there was no bond of sympathy. Their removal was urged, and a new plantation coveted. But the old master, wiser than the young man, insisted on the work being done "by halves." Half were accordingly destroyed, and new trees purchased at a cheap rate at an auction sale. They were planted, and are fine trees now, but they were not "true to name," and but for the old trees which were not destroyed the fruit supply for the establishment would still be far below the requirements.

Those are lessons which should not be lost. They speak with all the force of dearly bought practice. Never trust to cheap trees; never destroy the old until you have proved the new.

I have yet another example of the dangerous nature of "improvements" which involve extensive fruit-tree destruction. In the parish adjoining my abode is the seat of a nobleman of very high rank. He had other seats, and seldom was in residence here, yet here were the family fruit preserves. The trees were numerous, and, it must be admitted, ugly. They no doubt also impoverished much ground, but they also yielded tons of serviceable fruit. A young gardener was installed in charge. He was a persevering, industrious, and able man, but, like many others, judged too hastily, and "improved" too quickly. The old trees were to him an eyesore; their appearance could reflect no credit on his management; they lacked form, symmetry, and vigour. He longed for trees of modern mould which would reflect in their forms their manager's skill. These he obtained, but, unfortunately, before proving them he destroyed the old. Some he pruned, others he grafted, and many he uprooted. The following year the call for fruit could not be answered except by assurances of the precocious character of the new trees; but another year brought another failure, and then a third. The irate nobleman could endure it no longer, and the career of a promising young man was cut short by dismissal. The destruction of the old trees was unpardonable, and the misdirected energies of an able man were lost, his hopes of fame blighted, and he has since struggled on in obscurity.

I have said, Rather than destroy renovate. A great deal may be done in the way of old fruit-tree restoration that is left undone. The lichens are tolerated year after year to luxuriate on the branches, appropriating the juices of the tree, robbing it of sustenance, almost of life. The moss-covered bark of neglected trees has an analogy in the skin affections of animals, and neither can flourish so long as the evil is suffered to remain. The cleaning of the bark of old trees is directly beneficial, and if nothing further is done than that

their improved state becomes shortly manifest. Lichens are easily destroyed—first, if very bad, roughly scraping the branches and then dressing them thoroughly with fresh lime, dusting the trees when the branches are wet. Lime also mixed with water, in which at the least a pound of salt has been dissolved to each pailful, will destroy the parasites if applied in a thorough manner, and will not only not injure the trees, but cannot fail to be of the greatest benefit. The glaring white colour, if objectionable, may be toned down by soot, or a colourless bark-cleanser is afforded by a strong mixture of brine and soft soap. The removal of the exhaustive encrustation of moss, especially from the young branches, permits an increase of food to the tree both from the earth and air, imparting to it additional sustenance and strength, which it will show by healthier foliage and better fruit.

But that is not all that old trees require and deserve. They require pruning; some gently, some violently. On the heading-down of old fruit trees we may take a lesson from the plantations of forest trees. Who has not observed the vigorous upspringing of fresh growth from the old stools of recently felled broad-foliated deciduous trees and evergreens, the narrow-leaved kinds, as the Firs, being exceptions?

Fruit trees are amenable to the same mode of resuscitation. Healthy trunks of Apple and Pear trees in orchards, and Pears, Plums, and especially Peaches on walls will, if cut down to a convenient part, break fresh growth and cover space, and bear a given quantity of fruit much more quickly than will young trees. It is not always advisable to dismember the trees so thoroughly, but it is as well that we forget not that it may be done if necessary, as it certainly might be more frequently than it is, with undoubted advantage to trees and owners. It is well known that an old Apple or Pear tree of, it may be, a century old will, if grafted, put on a new head, grow vigorously, and bear after the manner of a young tree; yet do we not forget that if the old stem was not grafted that it would push fresh growth of its own kind, which would grow as freely as do the scions, of which it becomes the foster-parent?

Now for some more gentle pruning. Much has been said on the necessity of thinning the branches of old fruit trees. "Open out the centres of such trees and let the light and air do their beneficent work," is oft-repeated advice, and has a tempting sound. Here again the theory is good, but practice is needful to apply it to a profitable purpose. We must not go to work hastily and without due thought. First consider if it is possible that by exposing the interior branches of an old fruit tree, which have been enveloped in semi-darkness for half a century, to the sun and air we can clothe these old branches with fruitful spurs. In ninety-nine cases out of a hundred this hoped-for result is not achieved, and if the tree so operated upon is isolated, and on all sides exposed, the probability is that more harm than good is done by a violent thinning of its branches. I well know that I have done great injury to more than one old tree by an attempt to bring it to an ideal condition. I have cut away parts that were fruitful to admit light to the fruitless branches; but, as may be expected, after twenty years of waiting I find these branches (except at their extremities) fruitless still. I have thus not made the barren parts fruitful while I have reduced the fruit-producing parts of the tree. I was only a radical then and proceeded in a radical manner. I am older now, and have found that we cannot make the interior of a tree fruitful except by a full exposure of all its parts to the light and air from the first years of its existence.

An isolated old tree bearing heavy crops of useful fruit should be gently pruned by cutting away only unfruitful parts, leaving its outer surface as Nature has formed it, and the tree itself will present more leaves to the light and to a more profitable purpose, than we can effect by the "assistance" of thinning. That is what failures as well as successes have taught me in regard to old trees standing alone and exposed.

With trees that are sheltered, as in large orchards, danger by overthinning is not so great. Indeed, if a liberal thinning of the branches in such cases is followed by another important operation much good may be accomplished. If we can admit the light more freely we foster a shorter-jointed and more fruitful growth on crowded trees. But pruning alone will not do this; to be effectual it must be followed by the supplemental work of rubbing. Perhaps that is not an orthodox term and may not be found in the "Gardener's Dictionary" of the young professional; never mind, it is still expressive of the useful practice of an old practitioner. Suppose a man in the winter months takes one-third of the wood from an old

tree, what is the direct consequence of the thinning? It is this—From each "out" three, but more likely half-a-dozen, buds will push young shoots, and, if left alone, will form fresh branches, and in two or three years the tree is more over-crowded than ever. Thousands of trees, paradoxical as it may sound, have been made thicker by thinning; in fact, that is a result that must inevitably follow if the winter thinning is not followed by spring and summer "rubbing." Most essential is it this should follow the pruning of old trees, but seldom is it done. It simply consists of rubbing off the young growths that clothe the branches when such growths are about an inch long; it can be done by the finger and thumb, and a man will do more in half an hour to preserve the openness of the tree than we could accomplish in half a day with the saw and pruning knife. Winter pruning, if not followed by this simple summer dressing, is work only half done, or worse. When I see a tree unusually dense—its interior choked with a network of branches, useless and fruitless—I have always a suspicion that it is the result of "thinning;" rub off the after-growth and such a result never follows.

Something may be said on assisting the roots of "old trees;" also on the renovation of wall trees, for in these, too, I have made mistakes and seen mistakes made by others, which I will quote on a future occasion.

Mr. Luckhurst, the young-tree champion, is also an old tree-preserver. I happen to have seen Mr. Luckhurst's young trees, and I am not conscious of ever having looked at such trees at five years old. He, at any rate, does not defend the old because the young trees have failed him, and his testimony is, consequently, the more valuable.

One part of Mr. Luckhurst's letter is especially suggestive—that in reference to moss on the bark. He asserts that lichens do no harm on the "old bark," but urges their destruction on the "smaller branches." Do not we dress trees at the wrong end? How often do we find their stems limewashed, while the "smaller branches" are moss-covered? That is palpably wrong. I believe I have never expended my labour more profitably to my employer, and with greater benefit to his trees, than when, mounted on a tall ladder on a still, foggy morning, I have poured the lime dust among the fruit-bearing twigs, making them and myself as white as a miller. It is the tops of old trees that require dressing—those fruit-bearing parts which are so systematically left to the lichens, and the lower portions of the trees may take care of themselves.—**RADICAL CONSERVATIVE.**

PORTRAITS OF PLANTS, FLOWERS, AND FRUIT.

CUCUMIS SATIVUS var. *SIKKIMENSIS*. *Nat. ord.* Cucurbitaceae. *Linn.*, Monocladia Monadelphia.—The fruit is yellow, densely spotted with brownish red. Dr. Hooker says, "This singular form of the common Cucumber, though very commonly cultivated in the Eastern Himalayan Mountains, appears never to have been noticed horticulturally or botanically till I found it in Sikkim in 1848, and whence I brought drawings and specimens to England. These were described by N. Naudin in 1859, in his essay on the species and varieties of Cucumis in the 'Annales des Sciences Naturelles,' under the name of *Coneombre de Sikkim*; and he says of it that it is the most remarkable variety of the common Cucumber known to him, whether for the length or for the bulk of its fruit, which I have found to attain 1½ foot in length and a girth of 15 inches. It is grown in all parts of the Sikkim and in the Nepal Himalaya, up to 5000 feet elevation, in prodigious quantities. It ripens in July and August, or earlier at lower elevations, when the fruits are sold in the markets and eaten raw by the natives of all ages, as well as cooked. So abundant were they in the year 1848 that for days together I saw gnawed fruits lying by the natives' paths by thousands, and every man, woman, and child seemed engaged throughout the day in devouring them.

"The Sikkim Cucumber was first fruited in England by Major Trevor Clarke, who believed that he had fertilised it with the pollen of the Telegraph Cucumber. By some blunder, perhaps owing to the Melon-like appearance of Major Trevor Clarke's fruit, which was sent to Kew, and from which plants were raised, it is described in the *Gardener's Chronicle* as a hybrid between the Melon and the Cucumber—a cross which has never been effected. On its fruiting at Kew shortly afterwards I recognised it as my Sikkim plant, and the statement as to its hybrid origin was corrected in a succeeding number of the *Chronicle* (1875, vol. iv., p. 303). It flowered in the Tropical Economic House in July, and the fruit ripened in

August, when it attracted great attention from its size, singular form, and colour.

"In connection with this subject I may mention here that the origin of the common Cucumber, which is supposed to be unknown, is in all probability the *C. Hardwickii*, *Royle*, of the Himalaya Mountains, which inhabits the sub-tropical region of the range from Kumaon to Sikkim. This opinion, founded on specimens gathered by myself in the latter country, is also adopted by M. Naudin, upon the same materials (*Ann. So. Nat.*, l.c., p. 30). The flowers and leaves of the two plants are almost identical, but the fruit of *C. Hardwickii* is small, smooth, and very bitter; it is, however, striped with white and green, a very usual character with the Sikkim cultivated Cucumbers."—(*Bot. Mag.*, t. 6206.)

NICOTIANA TABACUM var. *FRUTICOSA*. *Nat. ord.*, Solanaceae. *Linn.*, Pentandria Monogynia. Flowers pink.—"A very little known plant, though introduced into England in the middle of last century, and admirably figured by Philip Miller, F.R.S., gardener to the Apothecaries Company's Botanic Garden at Chelsea, in his fine folio work illustrative of 'the most beautiful, useful, and uncommon plants published in his Gardener's Dictionary.' Miller describes it as growing naturally in Guinea, whence he received the seeds, and as being cultivated in the Brazils and sent to Europe under the name of 'Sweet-scented Tobacco.' Dunal, in De Candolle's 'Prodromus,' gives the Cape of Good Hope as its native country on the authority of Linnaeus, where, however, no species of the genus has been found in a wild state."—(*Ibid.*, t. 6207.)

MADEVALLEA SPHIPPIUM. *Nat. ord.*, Orchidaceae. *Linn.*, Gynandria Monandria.—"Dr. Reichenbach observes of it that it is a highly curious one; and it is indeed very different from any hitherto figured in this work, especially in the lateral sepals, that form a deeply concave bowl-shaped body, of a remarkable rufous-brown colour, and are thoroughly united even to the base of their long yellow tail-like tips, which curve away from one another in a singular manner. The inside of the united sepals is, moreover, traversed by five corrugated ribs or keels, that meet at the apex of the body, leaving deep concavities between them.

"I am indebted to Mr. J. T. Barber, of the Old Hall, Spondon, Derby, for this fine species, which he sent to Kew in March last, with the information that it was grown in a house with a day temperature of 65° Fahr., and a night one of 52° to 60°, and was watered but sparingly, a flower having been spoiled previously by over-watering. Dr. Reichenbach states that it was first discovered at Loxa by the late Dr. Krause, who sent it to Messrs. Backhouse, and that it has subsequently been obtained from Antioquia and Medellin by Mr. Wallis and others."—(*Ibid.*, t. 6208.)

BLANDFORDIA FLAMMEA var. *PRINCEPS*. *Nat. ord.*, Liliaceae. *Linn.*, Hexandria Monogynia.—A variety of *B. flammea*, but "for horticultural purposes it is a much finer plant. The bright crimson of the tube and pedicel form a very effective contrast with the bright yellow of the segments; so that, size of flower and colouring both taken into account, it may safely be said to be for decorative purposes the finest of the known Blandfordias. It was introduced by Mr. William Bull from New South Wales about 1873, and was exhibited by him at South Kensington in the summer of 1875."—(*Ibid.*, t. 6209.)

ANDROSACE SARMENTOSA. *Nat. ord.*, Primulaceae. *Linn.*, Pentandria Monogynia. Flowers pink.—"An interesting addition to the collection of rockwork plants, hardy and a very free grower. It is a native of the loftier regions of the Western Himalaya, and was first found in Central Nepal, whence it was sent to Dr. Wallich, then in Calcutta, about the year 1820, by the resident at the Nepalese Court, the Hon. E. Gardner. Since that period it has been found further west by Mr. Edgeworth, in Kumaon, at an elevation of 11-12,000 feet, and on the Zoji La Pass, north of Kashmir, by Dr. Thomson, at about the same height above the sea. Our plant was raised from seed collected by Dr. Bellew (who accompanied Forsyth's mission to Yarkand), at the same locality as Dr. Thomson's came from, and it was flowered first and beautifully by Mr. Isaac Anderson-Henry, at Hay Lodge, Trinity, Edinburgh, and subsequently at Kew, but in far less perfection than in the northern clime. As a spring bloomer, flowering in April, it will prove a most welcome accession to the hardy herbaceous border, and it is propagated with great ease by its runners, which spread all round the plant and hang over the sides of the pot in profusion."—(*Ibid.*, t. 6210.)

APPLE—*Paul's Imperial Crab*.—"Specimens of this very ornamental fruit were exhibited at South Kensington in

September, 1874, by Messrs. Paul & Son of Cheshunt. Fruit roundish oblate, about 1½ inch in diameter, with numerous shallow ridges, most evident towards the eye; stalk half an inch to three-quarters long, set in a moderately deep acute hollow; eye prominent, with long acute calyx-lobes, set in a broad shallow cup. Skin yellow, almost wholly covered with bright red, the outer part more deeply coloured, very deep crimson, with a thin bloom. Flesh yellowish, firm, tender, and moderately juicy, with a fresh and rather rough acidity.

"Messrs. Paul & Son have obligingly communicated the following particulars respecting this very ornamental fruit-bearing plant:—

"The Imperial Crab was a seedling raised by Mr. R. Laing of the Twickenham Nursery, a cross between the Red Astrachan Apple and Siberian Crab. As I understand Mr. Laing, it was accidental, the two trees standing with interlaced branches in one of the old walled squares of the nursery. It fruited, and was exhibited at the Pomological Society's meeting about the year 1865, where it was much admired, but did not receive any official recognition. Struck by the fruit on the young grafted trees, which I saw and admired three or four years successively, I persuaded Mr. Laing to let my firm send it out in conjunction with him. Hence when distributed in 1869 it became generally known as Paul's Imperial Crab. Its handsome foliage and vigorous habit, coupled with the brilliantly tinted fruit, have gained for it general favour. The fruit almost declares its parentage, so vividly is it coloured, while the Astrachan-Apple blood gives it the quality of being the earliest-ripening of the Crabs. It makes a handsome standard or free pyramidal bush. Miss Laing adds:—"The fruits preserved in various ways like the Siberian Crab make an agreeable and ornamental dessert dish; they may be also preserved like Morello Cherries, in gin, with a flavour of brandy, or boiled in syrup."—(*Florist and Pomologist*, 3 s., ix., 13.)

MELBOURNE HALL,

THE RESIDENCE OF W. D. FANE, ESQ.

MELBOURNE is a small market town of Derbyshire, containing about three thousand inhabitants; it is situated in the valley of the Trent, on the borders of Leicestershire. It is eight miles from Derby, and is easily reached by railway, since there is a branch line opened which runs through to Ashby-de-la-Zouch. The whole district is full of interest to the traveller. At Ashby-de-la-Zouch, only seven miles distant, are the splendid ruins of the old castle of the Zouches; while within an hour's walk of Melbourne Hall is Calke Abbey, the elegant residence of Sir John Harper Crewe; also Cole Orton Hall, so recently figured in these pages; and Staunton Harold, the costly seat of Earl Ferrers.

Melbourne is noted for its fertile market gardens. Strawberries are grown in great abundance, and we are told that forty tons are sent to Derby and other towns during the season. It is from this place that Viscount Melbourne derived his title, as well as the thriving city of Melbourne in Her Majesty's far-off dominions of Australia. It is remarkable that during the last twenty-six years Melbourne Hall has been the residence of two Prime Ministers whose titles have become extinct—Lord Melbourne and Palmerston.

The Hall, which is in the Italian style of architecture, was rebuilt by Sir Thomas Coke about the close of the seventeenth century, who served in Parliament and held important offices under Queen Anne. Sir Thomas so distinguished himself and became so great a favourite with his Sovereign that she presented him with a pair of vases that are placed in the gardens. The carriage entrance is a small enclosure entered through a pair of iron gates. At each side of the gates are two grand old Cedars. Passing through a narrow gate the visitor finds himself on a broad terrace walk, 24 feet wide, immediately in front of the mansion. Turning to the left is the lawn, laid out in separate terraces or parterres. Ornamental beds are cut out in the turf, and groups of shrubs and single coniferous plants, with vases and figures of fine sculpture, are judiciously arranged in different parts of the grounds. By the side of the central walk I observed some grand Red Cedars 25 feet high, equally fine Irish Yews, and several clumps of large Yuccas. At each corner of the upper terrace are two fine Deodars from 30 to 40 feet high, the largest being 90 feet in the circumference of its branches.

It is a remarkable fact that several other Cedars planted at the same time on the lower terrace, and only some 10 or 12 feet

from the same level, were killed during the severe frost of 1860, while those on the upper terrace survived.

On the lower terrace the first objects of interest are four Catalpas, fine deciduous trees for large lawns; the largest is 60 feet in the diameter of its branches. A little distance from this spot is a circle of grass, with a fine image of Mercury in the centre mounted on a massive pedestal. A little lower down is the pond or lake, but generally called the canal. At the opposite side of this sheet of water from the house I noticed an alcove formed of wrought iron of most elaborate design, and bearing the arms of the Coke family; it was like a huge birdcage, and had stood the storms of nearly two hundred winters. These lawns and terraces are encircled with a Yew hedge 12 feet high, and I mounted a ladder to ascertain the width at top, when I found the hedge to be 10 feet across. The lower part of the pleasure gardens are encircled again with a background of Scotch Firs planted in the time of William III., but many of them are fast falling into decay. Leaving the lower terrace we come to a spot where five walks branch in different directions: three of them terminate with fine sculpture, or bubbling fountains. Old alcoves are observed in recesses cut in the Yews, but restored from time to time.

Wandering on we find ourselves on a gentle eminence with a long and charming avenue at our very feet. Half-way down this long vista is a fountain perpetually playing. Turning a little to the right is a junction of three glades flanked by gigantic Limes cut every five years to the stumps. Beyond the first glade across the park is another vista, through rows of Spanish Chestnuts. From the second glade is another view cut through the park to catch a glimpse of the distant hills. On this eminence is placed one of the vases before named which was presented by Queen Anne. It represents the four seasons, and is one of the finest examples in modelling in existence. On the pedestal is the monogram "T. C.," of the Thomas Coke to whom this handsome present was given.

Turning to the left we reach the western terrace, and here the scene is entirely changed in character. In one part of the walk is the Elm avenue, though many of the trees are decaying with age. Down in a deep dell I noticed some fine specimens of *Pinus cembra*, very bushy, but not so proportionately high, for the leaders were frequently destroyed by late spring frosts. To the left is the large lake, 22 acres in extent, with a grand irregular margin, an island in the centre, and on its surface boats and waterfowl. In a secluded corner we come on a mineral spring, over which is erected a charming rustic grotto by the Hon. Mrs. G. Lamb, formed of tufa, stalactites, and spars, and bearing on a marble tablet over the water the following lines by the Hon. George Lamb:—

"Rest, weary stranger, in this shady cave,
And taste, if languid, of the mineral wave.
There's virtue in the draught; for Health, that flies
From crowded cities and their smoky skies,
Here lends her power from every glade and hill,
Strength to the breeze and medicine to the rill."

Passing through groves of deciduous trees and evergreens of every shade we cross a narrow brook that intersects the pleasure grounds in a subterranean culvert, and empties into the large lake at the lower end of the lawn in front of the mansion. Here we found a snug Rose garden; all the beds contained three rows of plants—standards in the centre and dwarfs on either side.

Another remarkable feature of these gardens is the Yew tunnel commonly called the Lover's Walk. It is formed of an avenue of Yews 150 yards long and 10 feet wide. It is a literal tunnel, for the branches are so grown and intergrown one into the other that it is only here and there that the ancient branches can be pierced with the rays of light. On the opposite side of the grounds is the library garden. At the top of the avenue of Wellingtonias and Cedars is the muniment room, where it is said that Baxter wrote his "Saints' Rest." On a low wall near to the conservatory is perhaps the largest *Wistaria* in England, its branches extending 800 feet. Formerly it extended 860 feet, but the large Cedars overshadowing its branches have caused them to die-off.

The kitchen gardens are about three acres in extent, and on the walls I noticed some good examples of Pears, Plums, Apricots, and Cherries. Round some of the quarters were bush Apples and Pears that produced good crops of fruit. Strawberries here are extensively grown, and from the appearance of the beds fine crops may be expected the coming season. The usual quarters devoted to vegetables I found as well

filled as they usually are in an ably-managed gentleman's garden. In the Peach house I noticed that the trees were planted about 4 feet apart, and trained as cordons up the rafters, and I was informed that by the system good crops of fruit are secured.

The church is in close proximity to the Hall, and presents more the appearance of a cathedral than a parish church. It is of the Norman period, and a fine example of that style of architecture. It is full of historic interest, and its many monuments and tablets are worthy of examination. In one of the vestries I saw an old will which has to be read once a-year from the pulpit, and for which the minister receives 5s.

I have dwelt longer on this grand old place than I contemplated. It would betray a want of gratitude on my part to conclude these notes without acknowledging the courtesy I received from Mr. Pearce, the highly respected head gardener.

and so on to the top, where the manure ought to be more decayed on account of the plants soon reaching it. If the surface soil is of a clayey nature, lay it up as rough as possible, and it will become pulverised, and its condition will be improved by the addition of mortar rubbish at the time of working it down for planting. Such beds in well-drained land would last for several years with the usual assistance in spring and summer cultivation; but if the beds are not to be permanent, a depth of 2 feet, with the bottom being broken up and manure added in the usual way, will be sufficient.

It is always best to select a piece of ground as open as possible and that is not permeated by the roots of trees. It is scarcely possible to work Asparagus soil about too much before the beds are planted, and that is why I advise the ground being prepared early; and as the proper time for planting is the latter end of March or April, according to the forward state of the weather, this will give fully two months for the soil to be thoroughly pulverised.

Fig. 11.—MELBOURNE HALL.

It is no mere compliment to Mr. Pearce to add that everything was in excellent keeping.—R.

NOTES ON VILLA AND SUBURBAN GARDENING.

PREPARING ground for Asparagus beds may very seasonably form one of the operations to be done now. It will be best, where two or more beds are to be made, that the whole of the ground be prepared at one time, because though it is customary to leave alleys of a certain width between each bed, the roots of the plants will occupy the whole space in time, and will therefore be benefited by that space being enriched as well as the other.

Asparagus delights in a rich, deep, alluvial soil, and if the soil is shallow or poor it must be made good and deep. Now, the question of depth much depends whether the bed is to be a permanent one, or whether the Asparagus is to be prepared by a few seasons' growth for forcing purposes. I apprehend that as this vegetable is so easily and inexpensively forced in spring that very few who grow it do not force it also; if so, the labour of making the beds is very much lessened, and especially in shallow soils; whereas, if permanent beds are made, most of the soil would have to be wheeled away and be replaced by a more suitable compost. I have enriched the soil to the depth of 4 feet in places where it could be done by placing a layer of manure at the bottom, and then digging it in and mixing it well as the work goes on; then a layer of soil and another of manure,

At the time of planting level the soil down as fine as possible, then take 3 inches of it off, lay it in the alleys, then lay the plants out in rows, spreading out the roots well, and when all is done return the soil in a careful manner. Do the work during a period of fine weather if possible.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

THE work is well forward in this department, and some ground that would have only been dug over will be trenched instead. It has been frequently stated that our ground is trenched and manured of necessity to support the crops of vegetables through the drought of summer. The light shallow soil resting on gravel becomes exhausted of moisture very speedily; and unless we either water copiously at a time when labour is most valuable to us, or trench and manure well at this time or in the autumn, the most valuable of the culinary crops are comparative failures. When it is necessary to water vegetables it is best to do it thoroughly, and mulch over the surface of the ground after. Heavy clay soil has its disadvantages, but for the general run of seasons it is by far the best for kitchen-garden crops. For the earliest crops the light soil has an advantage, as not only do the seeds vegetate more readily, but the plants grow more freely afterwards. But the owner of heavy soil may do much to forward his crops by careful preparation of the soil, and also,

by having a supply of dry light soil just to sprinkle along the drills to cover-in the seeds. A few barrowloads will go a long way. Soil from the potting shed, if it is sifted and reserved for this purpose, is as good as anything: it is often wheeled out to the vegetable-mould heap, or used in some way just to get rid of it. Heavy soil is also greatly improved by trenching, but too much of the subsoil must not be worked-up at once. In our early days we had some training in a garden where the soil was both deep and heavy. The gardener trenched deeply, but he had an opportunity to work-in any quantity of stable manure, with occasional dressings from the vegetable-mould heap. When the ground was dug in winter it was thrown up quite roughly or ridged; when this was forked over in the spring the surface was quite loose and in the best possible condition for cropping. The crops of vegetables grown in that garden were of the very best. An effort was made to have all the trenching and winter digging done as early in the season as possible.

The early Peas were sown before the frost, which came upon us rather suddenly on Wednesday night. The first crop of Carrots, Early Horn, are sown under ground vineries: this allows us to sow much earlier than it would be safe to sow in the open ground. Between the rows of Carrots Radishes are sown. The Olive-shaped or French Breakfast Radish is the variety most approved, and it is sown also in the open ground for successional gatherings. The Radishes are cleared off before they do any injury to the Carrots. During open weather the roots of Garlic and Eschallots may be planted out if they have not been planted in November. The ground should be slightly ridged, and the roots be planted on the ridges a foot between the rows and about 9 inches between the plants. It is best to plant on ground that has been well manured for the preceding crop. Lettuce will also be sown under glass in a few days. Hicks's Hardy White Cos is the best strain of Paris White Cos we have ever had. This variety also stands well over the winter months. The plants would not escape the sparrows unless the rows were covered with Pea-protectors.

PINE HOUSES.

We have a house of Queens, a few of which are throwing-up, and all of them will do so as soon as the bottom heat is increased. At the same time the temperature of the house will be raised to 66° at night, or even 70° in mild weather. The fruit will be ripe early in June; that throwing-up now will be ripe in May. Ventilation is carefully attended to even in dull weather, with a low temperature out of doors. The top ventilators are open a very little an hour before midday, and closed about 2 P.M.; if they are opened half an inch it will do the plants good. To keep up the temperature it is necessary to heat the pipes considerably; and until the days are longer it is better not to have the evaporating troughs filled with water—that is, if they are cast on the pipes. If they are moveable troughs they may be kept filled with water, as the heat does not act upon it sufficiently to cause much vapour under ordinary circumstances. Snuckers have been kept cooler than we liked to have them this winter; but it has kept them back, and they will not be ready to be placed in their fruiting pots for at least six weeks. The plants look very well, and will now improve rapidly.

CUCUMBER HOUSE.

Seeds were sown about two weeks ago, and the plants are now ready for potting-off, the soil for potting them being well warmed and moderately dried. The potting material at this season is turfy loam three parts to one part of leaf mould. The plants do best if they are placed on a shelf near the glass. When well established in the 48-sized pots the plants are ready for planting out. For winter Cucumbers the soil ought not to be deep, certainly not more than a foot. There ought also to be plenty of drainage underneath; and before the compost, which ought to be open, is placed over it, some turf with the grass side down must be laid over the drainage to prevent the compost from mixing with it. When the soil has been in the house a week the plants may be put out. The trellis to which they are trained should be a foot from the glass. Sometimes the trellis is made of wood, but this causes it to be necessarily heavy, and to exclude light. A light trellis of ironwork is much better. It is a little more expensive at first, but much more convenient, to have the trellis made moveable.

STRAWBERRIES.

We have placed a second lot of Black Prince in an early vinery with a temperature of 55°. We would rather that it had been 45° to begin with, but the temperature cannot be altered for a few Strawberry plants. There is plenty of atmospheric moisture, and as soon as the plants are fairly started, which will be before they are at all shaded by the Vines, the plants will be removed to the Pine house. We still grow Black Prince for the earliest; it is always sure to carry a crop, however early the plants may be started. The next in succession is Keens's Seedling, followed by President. Strawberries will stand a good deal of hard forcing if the plants are placed near the glass.

PLANT STOVE AND ORCHID HOUSES.

We frequently allude to temperature in the plant stove. Our house has been kept this winter at 60° for a minimum, with a

rise of 5° by day, or 10° if the days have been mild with a little sunshine. The days and nights are now cold with cutting east winds, and the lower temperature only has been kept up. In our house are a few Orchids, such as *Phalanopsis* and *Oypripediums*, that require a winter temperature of 60° to 65°. *Nepenthes Rafflesiana* also requires a high winter temperature. The bulk of the plants would be much better in a temperature of 55°: they rest better, are more easily kept free from insect pests, and start more strongly into growth when a higher temperature is kept up from the 1st of March onwards. *Poinsettias* that have finished flowering, or rather that have lost their floral bracts, will be removed into a house with a lower temperature and rather drier atmosphere. They have made a splendid show for us this year. We had scores of heads with from thirty to forty floral bracts to each, and that measured from a foot to 15 inches across.

We commence repotting specimens of any hardwood plants that require it this month, and would already have done so if the weather had not changed. If it is intended to make handsome specimens of the plants the potting must be done carefully, and suitable compost must be used. *Dipladenias*, *Rondeletias*, *Passifloras*, *Euphorbias*, and indeed the largest proportion of hardwooded stove plants, thrive best in a compost of about two parts turfy peat to one of turfy loam. Both the loam and peat should be laid up about three months before using it. We find *Ixoras* do best in turfy peat without any other ingredient, except, of course, silver sand if it is required; but there is sometimes peat to be found that contains naturally a sufficient proportion of sand. *Franciscea*s succeed well in turfy peat, a little leaf mould, and sand. A very large proportion of the softwooded plants do best with a little leaf mould added. All decaying wood should be picked or sifted out of it. The roots should be well watered if necessary a day before repotting, as the longer the plants will stand without any water being applied to the roots after repotting the better.

Orchids require all the light it is possible to give them at present. Some *Lælias* and *Cattleyas* have just completed their growth; others, such as *Cattleya Warneri*, *C. gigas*, &c., are starting into growth. In either case light and an increased temperature is necessary. The above have been placed in a house with a night temperature of 60°. *Cattleyas*, *Lælias*, *Dendrobiums*, &c., at rest are in a house from 50° to 55° at night. Cleanliness everywhere on plants, paths, and stages, as well as the glass and rafters, is all-important.

FLOWER GARDEN.

The fine weather urged us to be attending to the borders of herbaceous plants, some of which are now starting into growth, and the young shoots in mild weather are a prey to slugs and other depredators. We do not expect many flowers at this season; the *Chrysanthemums* have just been removed, but a few *Violets* are to be found. The *Christmas Rose* is in full beauty; *Jasminum nudiflorum* and *Chimonanthus fragrans* on walls should be in every garden. *Roses*, dwarfs and standards, are safest with some nice rotted manure round the roots. The buds are starting freely, but it is wisest not to prune until near the end of February. *Dahlia* roots must be examined, as the old stalks that have been left on sometimes decay and destroy the eyes at the base. We are preparing fermenting material for a frame which will hold cuttings of *Verbenas*, *Lobelias*, *Ageratum*s, and other bedding plants. We have also been repotting zonal *Pelargoniums*, pricking *Lobelias*, &c., out in boxes. They are better to have a little heat until established.

—J. DOUGLAS.

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

BRIGHTON (Spring Show). March 22nd and 23rd. Mr. G. Wehley, Holm Wood, Westbury-upon-Trym, Hon. Sec.
ROYAL CALLEDONIAN HORTICULTURAL SOCIETY. Shows April 5th, July 5th, and September 18th.
WESTMINSTER AQUARIUM. April 12th and 13th, May 10th and 11th, May 30th and 31st, July 5th and 6th, October 4th and 5th.
MAIDSTONE (Roses). June 21st. Mr. Hubert Bensted, Roekstow, Maidstone, Sec.
SPALDING. June 21st. Mr. G. Kingston, Sec.
SOUTHPORT. July 6th, 7th, and 8th. Mr. E. Martin, Sec.
HLENSBURGH (Roses). July 19th and 18th. Mr. J. Mitchell, Sec.
BRIGHTON. July 29th. Messrs. C. Jessop & E. Rawnsley, Hon. Secs.
DUNDREE (International). September 7th, 8th, and 9th. Mr. W. E. McKelvie, 26, Euclid Crescent, Sec.

TRADE CATALOGUES RECEIVED.

Francis & Arthur Dickson & Sons, 108, Eastgate Street and "Upton" Nurseries, Chester.—*Catalogue of Vegetable and Flower Seeds, &c.*

Hender & Sons, Plymouth.—*Illustrated Catalogue of Vegetable, Flower, and Agricultural Seeds.*

Thomas Bunyard & Sons, Maidstone.—*Descriptive Catalogue of Vegetable, Flower, and Agricultural Seeds.*

The Pine-Apple Nursery Company, Maida Vale, London, W.—*General Catalogue of Garden and Farm Seeds, Gladiolus, Bulbs, &c.*

Smith & Simons, 86, Howard Street, St. Enoch Square, Glasgow.—*Cultural Guide and Descriptive Seed Catalogue.*

G. O. Short, Market Place, Stokesley.—*Descriptive Catalogue of Vegetable and Flower Seeds.*

Louis Van Houtte, Royal Nurseries, Ghent, Belgium.—*Catalogue of Gesneriaceous Plants, Begonias, Dahlias, Roses, &c.*

TO CORRESPONDENTS.

.. All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (E. J. J. E.).—Macintosh's "Book of the Garden," and the "Cottage Gardener's Dictionary" (J. Brown).—Gordon's volume "The Pinetum," describes all the Conifers, but there are no plates. In Loudon's "Encyclopaedia of Plants" there are woodcuts of the foliage and cones, and of flowering plants.

DOCTOR HARVEY APPLE (H. L. E.).—It is not the same as "Waltham Abbey Seedling." This is a modern variety, but Doctor Harvey is one of the oldest. Parkinson in the reign of Queen Elizabeth describes it as "a faire, greate, goodly Apple, and very well relished." You are correct in saying it is "one of the best cooking Apples."

PEARS NOT RIPENING (F. Holloway).—The pyramidal-shaped Pear is *Beurré Rance*, and the other *Jean de Witte*. We think you gather them too soon, and keep them in a room too warm.

WILD FLOWERS (G. S.).—We cannot say more than that they will conclude when all our native flowers have been included.

MUSHROOMS IN CUCUMBER HOUSE (H. W.).—The temperature required for Cucumbers is too high for the growth of fleshy Mushrooms, but they would, nevertheless, grow, but be poor as compared with those grown in a lower temperature. You will need to have a bed of fresh horse droppings a foot thick, and beaten very firm, and when the temperature of the droppings has subsided to 80° you may then insert pieces of spawn not less than an inch or larger than 2 inches square. Insert these 2 inches deep, and make the surface of the bed again firm after filling-up over the spawn. In a week after spawning cover the bed with soil in a moderately moist state, so that it may be beaten firm and smooth, the soil being good turfy loam and 2 inches thick. The Mushrooms will appear in about six weeks, when the bed is to be kept moist, avoiding overwatering. The pieces of spawn should be inserted about 9 inches apart, and for the size of the bed you name you will require about two bushels of spawn, or a "brick" per square yard. We shall be obliged by particulars of the heating from the kitchen range.

REPORTING STAGE PHALANGIUMS (A Subscriber).—Report them now if they have already been stopped; but if not stopped, do so now, and report about the middle of February, giving them their blooming pots; and by paying attention to tying out the shoots and affording a light position with free air-giving, watering carefully, and applying liquid manure when the pots are filled with roots, you will obtain a quantity of bloom. Keep cool, but safe from frost.

FUCHSIA FOR EARLY FLOWERING (Idem).—Out in the plants and place in the temperature you name, and when they are making fresh shoots report, keeping moist by sprinkling overhead morning and evening, and watering carefully at the roots until those are working freely in the fresh soil, then supply water more freely. Shift into the blooming pots when the roots are showing at the sides of the pots.

SELECT FANCIES (G. F.).—*Scylla*: Locomotive, Mrs. Horaburgh, Mrs. Knight, Cherub, Finale, and Masterpiece. *Fancy*: Lady Boss, Miss Macneeking, Rev. H. H. Dombrian, William Baird, Pandora, and Little Kittie. The best mode of striking cuttings is either under hand-lights or in cold frames in light soil with a fourth of silver sand, taking the young side shoots, and inserting in April or May for autumn flowering, and in August or early September for spring. Particulars of treatment are given in "Florists' Flowers," which may be had free by post from our office for five penny postage stamps.

PLANTS FOR NORTH WALL (W. H. Midwinter).—There are no flowering plants suitable for a north wall except, perhaps, *Jasminum nudiflorum*, which succeeds well and flowers at this season. *Cotoneaster microphylla* has very neat evergreen foliage and fine red berries, but does not flower well against a north wall. *Ampelopsis Veitchii* is a neat plant for a north wall, also *A. heterocarpa*; but the finest of all plants for a north aspect are *Ivy*, which in the green and variegated forms are very handsome.

GRAFTING *PIROA NOBILIS* (C. J. D.).—It may be successfully grafted, but the plants are never so shapely as those grown from seed, though if leaders are employed for grafting there is no great difference between grafted and seedling plants. The stock most commonly employed is the common Silver Fir (*Picea pectinata*), and the time to operate is in March or April just before the tree from whence the scions are taken commences to swell its buds. Budding is not, that we are aware, resorted to, and neither it nor grafting are desirable modes of propagating this finest of the *Piceas*. *Arctostaphylos* is not grafted. All Conifers of horizontal side-branching habit are best from seed.

EUCALYPTUS AMARONICA IN GREENHOUSE (Amateur).—This very desirable bulbous plant cannot be grown satisfactorily in a greenhouse. It requires a stove temperature—a brick moist heat when growing, and to be rested in a cooler and drier atmosphere. Unless you decide to have your house divided,

and one of the compartments kept at stove temperature, we should advise you to discard the *Eucalypta*. Your method of heating is of the worst kind. We should obtain a stove boiler and fix it either inside the house or in an outhouse, having 2-inch hot-water pipes, of which you will require two rows—i.e., a flow and return, along two sides and one end, or both if you have not a doorway at the end, or all around excepting doorway, or an equivalent of four rows in front and at one end. If you have a division for the stove compartment you would require double the quantity of piping. The fruit trees in pots may be introduced to the greenhouse early in next month.

SELECT BRONZE PHALANGIUMS (J. M.).—Black Douglas, Mrs. Harrison Weller, Prince Arthur, Rev. C. F. Peach, W. E. Gumbelton, and W. R. Morris.

SALT FOR DESTROYING WEEDS (An Eleven-years Subscriber).—We have not noted the particular quantity per square yard required, but we should think about 2 lbs. It is best applied during dry weather in April or May. It is not, however, nearly so good a weed-destroyer as that noted at page 588 of last volume in answer to "J. R." which see.

LEEK AND CELERY FOR EXHIBITION (Idem).—Ayrton Castle Giant Leek is a fine large kind, but we have it this year surpassed by "Carantan." Of Celery, Leicester Red (Major Clarke's Solid Red) is a fine red, but a larger is Ivory's Nonsuch Pink. Williams's Matchless White is very good, a larger white kind being Seely's Leviathan. Sow the Leek outdoors in March, and the Celery in gentle heat early in March, keeping near the glass to prevent the seedlings drawing, and prick-out in good rich soil outdoors in a sheltered situation when the seedlings have a pair of leaves besides the seed leaves.

VINES AND STRAWBERRIES (Constant Reader).—You should plant Alicante instead of Buckland Sweetwater. Muscat Escholata is similar to Muscat of Alexandria. You might plant the fruiting cane of Alicante and fruit it this season, but do not shake out the roots, as it will be necessary for you to do with those Vines intended to be permanent. The Strawberry plants in pots and the Peach trees in pots would both succeed in the warm house. Place the Strawberry pots on a shelf near the glass. They will do better if you can start them in a low temperature with the Vines to begin with.

FRUIT TREES FOR WALL (West Coast).—On the highest portion of the wall plant Royal George Peach and Pine Apple Nectarine. The trees ought to be 30 feet apart. We name three of each sort, and advise you to plant the *Plums* or *Pears* on the wall facing south-west. *Peaches*: Royal George, Early York, and Bellegarde. *Nectarines*: Pine Apple, Elrune, and Victoria. *Plums*: Green Gage, Jefferson, and Coe's Golden Drop. *Pears*: Louise Bonne of Jersey, Marie Louise, and Doyenné du Comice. *Cherries*: May Duke, Black Tartarian, and Elton. It is better to have them worked on the free stock for walls. Pyramid Apple trees would come into bearing in two years. Plant the trees 9 feet apart. They would probably last forty or fifty years.

ROSES IN ENGLAND (J. A. C.).—Roses were sold in the flower market of Athens, and many varieties of Roses were cultivated by the Romans. They, we have no doubt, introduced them into England, and had them in the gardens of their numerous villas here. In the fifteenth century the Red and White Roses were the distinguishing badges of the Royal houses of York and Lancaster; and Lyte, the earliest of our writers on plants, in 1578 names many varieties as then cultivated in our gardens. Linacre brought to us from Italy in 1624 the Damask Rose.

GRAFTING (G. W. J.).—We know of no special work on the subject. The directions in our "Fruit Garden Manual" are sufficient, and you can have it for five postage stamps.

ASPLENIUM TRICHOMANES VAR. MAJUS (G. McDougall).—Mr. Lowe does mention this, but says that it is a large growth of the normal form. The climate of Devon increases the size of the original.

DIPLADENDIAS, &c., FOR FLOWERING IN JULY (Amateur).—Much depends on the heat at your command, and the character of the summer. About the second week in February would be a good time to start the plants, regulating the heat according to their growth.

NAMES OF FRUITS (E. M. Stone).—105, Chantrelle; 249, Gillogil (N.B.)—*Pears*—1, Zéphirin Grégoire; 2, No Fins Meuris; 3, Doyenné Goubault; 4, Grassanne. *Apples*—1, Salwood's Ratnet; 2, Not known; 3, Golden Harvey; 4, Pearson's Plate. (W. F. G.).—1, Hollandbury; 2, Bess Pool; 3, Claygate Pearmain; 4, Not known; 5, Winter Greening; 6, Delaware.

NAMES OF PLANTS (S.).—*Viburnum*: *Tinus*. The Conifers cannot be named from the scraps sent. (Camel).—1, *Adiantum tenerum*; 2, *Pellaea hastata*; 3, 4, forms of *Selaginella Martensii*; 5, *Fexia cocinea*.

POULTRY, BEE, AND PIGEON CHRONICLE.

BRISTOL POULTRY SHOW.

(Continued from page 17.)

BRAHMAS.—The Dark cockerels mustered twenty-nine entries. First (Lingwood), a neat bird of beautiful colour, and well grown. Second (Hamilton), a well-shaped bird, but getting a little yellow in the saddle. Third (Lingwood), a stout chicken, but rather inclined to be coarse in comb. Fourth (Lyon), was a nice bird. Pen 818 (Wright), highly commended, was a pretty bird, neat in comb, the best coloured bird in the class; but he is rather narrow, and wants time. Pen 822 (Le Seur), highly commended, was also a good bird. Pullets.—First (Percival), pen 857, a prettily pencilled bird, but small. Second, 868 (Lingwood), a fine well-shaped pullet, with nice markings. Third (Newnham and Manby), a good pullet, and deserved her position. Fourth, 860 (Percival), a moderate bird, tolerably pencilled, but small and deficient in leg-feathering. We liked many pens in the class much better. The Hon. Miss D. Pennant and the Rev. J. D. Peake showed birds we preferred. Pen 851 (Ansdell), unnoticed, we thought a good bird; she was well feathered, and a splendid colour, and as size has not been a very great consideration with the Judges in their Brahma pullet awards this season, we think they might have placed her in the prize list. In old cocks Mr. Lingwood was again first with a grand bird; Mr. Ansdell

second with a neat bird of good colour; and Miss Pennant's bird well deserved the third prize. Pen 875 was commended: we could not understand why he obtained this distinction. Pen 382 (Rev. R. G. Watson), a fine bird, was disqualified on account of the tail being "stained and dressed." Hens.—First and cup (Newham & Mauby), a fine well-marked hen. Second (419, same owners), a fine hen, but not so well feathered in the leg as the first-prize pen. Pen 403 (Rev. J. D. Peake) was third, but we liked Mr. Lingwood's pen (387, very highly commended) in many respects much better.

Light.—The cockerels only numbered eighteen entries. Mr. Lingwood was first with the bird we admired so much at the Palace, and which only there obtained the fourth position. Mr. Leno showed a good bird that was second. Third (Webb) looked a little creamy. With the exception of the winner we thought them a very moderate lot. Pullets were more numerous and a better class than the cockerels. Mr. Haines was first with a fine bird, good in colour and well marked in the hackle. Mr. Leno was second with a good bird, but the white was not so pure; and Captain Savile's bird obtained the third prize: we think we should have transposed their positions. Mr. White's fourth-prize pen was good in colour but small. Pen 438 (Widdowson), highly commended, and pen 439 (Webb), very highly commended, we admired very much. Cocks.—Mr. Lingwood's first-prize bird deserved his position. The second we did not admire. The third pen, 481 (Haines), pen 479 (Percival), highly commended, and others we thought in many points his superior. Hens.—First (Mrs. A. Tindal) a grand bird. We think we have seen her before and noticed a peculiar curl or twist in all the saddle feathers as they reached the tail; it is a great defect. In other respects we think her unapproachable. Pen 494 (Turner) was second, in splendid condition; third (Watson) a good hen. We also liked much pen 506 (Rev. R. G. Watson).

NORWICH SHOW OF POULTRY, &c.

THE first Show of the Central Norfolk Poultry Club took place on the 5th and 6th inst. in the Corn Hall at Norwich. The building is a splendid one for such a purpose, the light being equal and good. Billett's pens were used on this occasion. Unfortunately some capital pens arrived too late for competition, but the number of empty pens was unusually small. The entries numbered 501, the quality of the poultry especially being exceedingly high.

Dorkings headed the list with four classes, the Dark Greys being very good in every respect, but the other varieties were poor, with the exception of those from Mr. Wren, which were, however, as before stated, too late. The cup was awarded to a Dark Gray cock. **Cochins**, four classes: Buff cocks, first-and-cup, as well as cup for the county, a grand rich even cockerel; second a cock good in shape, but not equal in colour. In hens (Buffs) were some grand birds, large, shapely, and in fine order; the second losing in colour only. Any other cocks, first a massive Partridge, a shade too dark in colour for our taste; second smaller but good. In hens, which was not one of the best classes, first was a very good Partridge, and second a White pullet. **Brahmas**, four classes: cocks, Dark, first-and-cup and members' cup a very large cock, closely pressed, however, by more shapely and better-marked birds. Hens: a handsome pullet first, second a hen; a fair class. Light cocks a good lot, the first a most perfect bird, second close upon it. Hens a nice lot also. In *Spanish* were some very good birds, and the competition close; the first cock won the cup also, and is a bird that must make his mark; second a bird little inferior. Hens very fine, and little to choose in the three first birds. *French* a fair lot, the winners *Crêves*. *Game*, Black Red cocks were a fair lot, but not as good as we could have expected, and little to choose between the lot. Hens, Black Reds, better than the cocks. Brown Red cocks poor except the winners, which were both cockerels. Hens of that colour but four, and these good. Duckings were very good, and the cup and county cup was won here by a grand pen of birds. Piles poor except the first-prize cockerel. *Hamburghs*, Gold-pencils, but a moderate lot; the Gold-spangles better; the Silver-spangles by far the best, and the cup awarded to a grand pen of young birds. Black *Hamburghs* were pretty good, although some had defective combs. *Bantams* were placed too high to show to advantage. Both the cocks and hens of the Black Red varieties were good, the winners very gamey and close in feather. The gems, however, of the Bantam section were the pen of Duckings to which was awarded the cup; the next in point of quality the Piles, which were, however, looking somewhat flat. The variety of Bantams were a large class, and two firsts were allowed, one going to a pen of Gold Sebrights and the other to Blacks, the second also being Blacks. There was one good pen of Booted. Any other variety were first-and-cup Gold Polands, second Malays, and very highly commended Gold Polands.

Aylesbury Ducks only two pens; *Bouens* more numerous and good, while the Variety class contained Malays, Mandarins,

and Whistlers. There were some very large *Geese*, *Toulouse*, but not the best in colour. *Turkeys* good, the cup awarded to them. The quality of the local birds ran very high, in many cases the cups for open competition being won by these exhibits. The Selling class was large, but we cannot say much for the quality.

Pigeons were fair classes, but the quality not so good as we expected to find, the Carriers being positively poor; but the Dragoons a grand lot, the first award going to heavy soft-fleshed-eyed birds, not at all to our taste, but evidently the London style. These were Yellows, very good in all other points; second a good pair of Silvers, scarcely decided as to colour of bars. Antwerps poor except the first Silver. Bars a moderate lot, and mostly Blacks. In Pouters Whites won the prizes, these being in the height of condition. Fantails good, but would have been much better shown singly. Tumblers, Almond, a good class, as also the Any other variety, in which pen 440 was disqualified, else the cup for the section would have been awarded here. The cause was a wing feather marked, for what purpose we know not, but to say the least it was a grave oversight. Jacobins only poor as a lot, first White and second Yellows. The Variety was a capital class, some good Owls both foreign and English, Trumpeters, Frillbacks, and Archangels being shown. The Selling class was poor.

DORKINGS.—Coloured.—Cock.—1 and Cup, T. & H. Heath, Norwich. 2, C. Loring, Gillingham Rectory. *viz.* J. Ward, *ac.* Rev. E. Bartram, Henry Lingwood, E. H. Witlet, *c.* J. C. Davies, Mrs. Berners, H. A. Riggs. Hen.—1, Rev. E. Bartram, Berkhamstead. 2 and *ac.* Mrs. B. B. Sapwell, Aylsham. *viz.* B. Lingwood.

COCHINS.—Any other variety.—Cock.—1, T. & H. Heath. 2, C. Loring, *c.* J. E. Plagim. Hen.—1, T. & H. Heath.

COCHINS.—Cinnamon or Buff.—Cock.—1 and Cup, Lady Gwydyr, Ipswich. 2, Mrs. C. Berners, Yorkford. *ac.* T. Aspley, Henry Lingwood, *c.* Rev. C. Gilbert, Henry Lingwood. Hen.—1, Lady Gwydyr. 2, Lieut.-Col. Bignold, Norwich. *ac.* T. Watson, Lieut.-Col. Bignold (2). *c.* Mrs. C. Berners.

COCHINS.—Any other variety.—Cock.—1, Lady Gwydyr. 2, G. E. Porter, Sandy. *ac.* G. B. B. Breese, *c.* G. B. C. Breese, Lieut.-Col. Bignold (2). Hen.—1, T. Aspley, Ayrington. 2, Lady Gwydyr. *ac.* F. Bullard, Lieut.-Col. Bignold, G. B. C. Breese.

BRAHMAS.—Dark.—Cock.—1, Horace Lingwood, Creeting, Needham Market. 2, Mrs. H. E. Buxton. *ac.* Lady Gwydyr. *c.* W. Holmes, Newham & Mauby, Major G. J. Ewen, Rev. C. Gilbert, H. Saberton. Hen.—1, Lady Gwydyr. 2, J. S. Pearson, Great Melton. *ac.* Horace Lingwood, Mrs. Berners, E. H. Witlet. *c.* W. Branton, W. Holmes.

BRAHMAS.—Light.—Cock.—1 and Cup, Horace Lingwood. 2, F. Haines, *ac.* F. Haines, H. Watson. *c.* E. V. Snell. Hen.—1, Horace Lingwood. 2, F. Haines. *ac.* Mrs. Feal, *ac.* H. Bird, *c.* E. J. Bird.

SPANISH.—Cock.—1 and Cup, W. J. Nicholas. 2, S. J. F. Stafford, Great Yarmouth. *ac.* and *ac.* F. Waller. *c.* J. T. Dixon, R. Blower. Hen.—1, F. Waller, Wood Green, London. 2, W. J. Nicholas, Saffron Hill, London. *ac.* H. E. Buxton, *ac.* H. Holmes, H. J. Liddow.

PARTRIDGE.—1, W. J. M. Cullick, Littleport. 2, A. W. Darley, Bury St. Edmund's. *c.* W. H. Hackblock.

GAME.—Black Red.—Cock.—1, L. Walter, Newark. 2, W. Wainwright, Warwick. *ac.* J. Mason. *ac.* T. L. Fellowes (2). Hen.—1, H. E. Martin, Fakenham. 2 and *ac.* P. Paynton, Norwich. *c.* F. Simpkins, J. C. Davies, J. Mason, W. Long.

GAME.—Brown Red.—Cock.—1 and 1, H. E. Martin. *ac.* R. H. Gillett. Hen.—1, H. E. Martin. 2 and *ac.* R. H. Gillett, Halvergate. *c.* W. Long.

GAME.—Duckings.—1 and Cup, H. E. Martin. 2, T. Doores, Colchester. *ac.* D. W. J. Thomas. Pile.—1, P. Paynton. 2, J. Osofort, Ilkeston. *c.* H. R. Edmund, P. Paynton.

HAMBURGH.—Gold pencilled.—1, W. K. Tickner, Ipswich. 2, Col. Cockburn, Norwich. *ac.* R. Brown, A. Silver, H. Pickles. Gold-spangled.—1, W. K. Tickner. 2, H. E. Martin. *ac.* R. Brown, A. Silver, H. Pickles.

HAMBURGH.—Silver pencilled.—1, H. E. Martin. 2, H. R. Plattin, Jun. Fakenham. *c.* F. W. Meynell. Silver-angled.—1 and Cup, Rev. T. L. Fellowes, Norwich. 2, H. Pickles. *ac.* Holmes & Deane. *c.* C. Loring, T. E. Thurtle, H. R. Plattin, Jun.

HAMBURGH.—Black.—1, T. A. Wright, Great Yarmouth. 2, J. F. Case, Testerton Hall. *ac.* H. R. Plattin, Jun. H. Pickles.

DUCKING.—Black.—1, Cup, and *ac.* A. & W. B. Silvester, Shalfield (Gold Polands). 2, T. A. Wright, Great Yarmouth. *ac.* J. F. Stradford (Brown Malays), Rev. C. Gilbert (Malacca Game). *c.* Rev. W. C. Stafford (White Leghorns), F. P. Smith (Leghorns), E. A. Beles (White-crested Black Polands), J. F. Breese.

GAME BANTAMS.—Black or Brown Red.—Cock.—1, F. Bennett, Ipswich. 2, W. Adams, Ipswich. *ac.* H. E. Buxton, W. Adams, J. S. Pearson. Hen.—1, J. S. Pearson. 2 and *ac.* F. Bennett. *ac.* J. S. Pearson, C. E. Dade, W. Long (2).

GAME BANTAMS.—Duckings.—1 and Cup, W. Adams. 2, J. S. Osofort. Pile.—1, E. Brownlie, Kirkcaldy. 2, J. Osofort. *ac.* J. S. Pearson.

BANTAMS.—Any other variety except Game.—1, R. H. Ashton, Manchester. Extra 1, W. Holmes, Thetford. *ac.* Rev. J. C. Martyn, W. H. Hackblock, T. J. C. Rackham, W. Durrant (2), W. Adams, A. Vander Moerssch. *c.* F. Bullard, E. Woods, W. H. Hackblock.

DUCKING.—Aylesbury.—1, E. V. Snell, Barrowden. 2, H. Hoff, Lynn. Rouen.—1, Mrs. C. Berners. 2, F. N. White, Norwich. *ac.* E. V. Snell, S. H. J. Garney, Rev. W. C. Safford, Rev. T. L. Fellowes, Mrs. H. E. Buxton, H. Densett, *c.* T. H. Heath, R. H. J. Garney. Any other variety.—1 and *ac.* A. & W. B. Silvester. 2, F. Bullard, Norwich (Caroline). *ac.* W. H. Hackblock (Cayuga), F. Bullard (Mandarins). *c.* S. W. Stafford (White Muscovy).

GREEN.—1, J. P. Case. 2, Mrs. Thornhill, Thetford. *ac.* E. V. Snell, E. J. E. J. Garney.

TUMBLER.—Black Norfolk.—1, H. J. Gunnell, Milton. Any other variety.—1, Cup, and *ac.* H. J. Gunnell. 2, Mrs. A. Mayhew, Great Baddow.

NORFOLK SPECIAL PRIZES.—1 and 2, Mrs. B. B. Sapwell (Coloured Dorkings). *ac.* T. & H. Heath (Silver-Gray Dorkings), G. Warner (Brahma-Dorkings), T. Norton (Dorkings).

PHREASANTS.—1, F. Bullard, Old Catton (Silver). 2, H. Colbeck, Harleston (Golden).

SELLING CLASS.—Cock or Drake.—1, W. Durrant, Great Yarmouth. 2, Miss M. E. Campden, St. Nicholas (Aylesbury drake). *ac.* A. & W. B. Silvester. *ac.* Mrs. B. B. Sapwell (Coloured Dorking), Rev. W. C. Safford (Rouen drake). *c.* J. Ewen (Dark Brahma), P. Haines (Light Brahma), W. Carter (Black Spanish), E. Holmes (Black Spanish), H. Densett (Brahma), L. Wren (Dark Brahma), F. Bullard (Mandarin drake), T. A. Wright (Black Hamburgh), *c.* Rev. W. C. Safford (White Leghorn), H. E. Martin (Brown Red), Mrs. Griggs (Cuckoo Japanese Bantam).

SELLING CLASS.—Hens of Ducks.—1, A. & W. B. Silvester. 2, F. Rackham, Norwich (Black Cochins). *ac.* J. N. Waite (Dorkings), W. Carter, A. & W. B. Silvester. *ac.* W. White (Black Spanish), G. S. Pearson (Dark Brahma), Mrs. C. Berners (Coloured Dorkings), H. Densett (Brahma), F. Bullard (Mandarin Ducks). *c.* C. J. Ewen (Dark Brahma), Rev. C. J. Martyn (Light Brahma), E. Holmes (Spanish), Mrs. Griggs (Dorkings), W. Branton (Brahmas).

PIGEONS.

CARRIERS.—1, H. M. Maynard, Holmewood, Isle of Wight. 2, T. Roper, Berham, Ipswich. *etc.* H. M. Maynard, H. J. Nichols. *Ac.* H. Thurlow (3).
DRACOONS.—1, Cup, and 2, F. Graham, South Birkenhead. *etc.* R. Woods (3).
Ac. A. W. Wren. *c.* W. Smith. F. Graham.
ANTWERPS.—1, J. B. B. Birmingham. 2 and *Ac.* Hon. G. M. Sutton, Thrice Square, London. *etc.* C. Gamon (3).
BARBS.—1 and 2, H. M. Maynard. *etc.* P. H. Jones. *Ac.* A. P. Byford, F. Waller.
POUTERS.—1, H. Thurlow, Burnham Market. 2, L. & W. Watkin, Northampton. *Ac.* W. Nottage, H. Reynolds.
FANTAILS.—1, J. F. Lovelands, Newark. 2, J. Walker. *etc.* and *Ac.* H. M. Maynard.
TUMBLERS.—1, J. E. Palmer, Peterborough. 2, H. Yardley, Birmingham. *etc.* W. Nottage, L. E. Willett. *Any other variety*.—1 and *etc.* L. E. Willett, Norwich. 2, H. Yardley. *Ac.* A. Vander Meersech.
JACOBIANS.—1 and 2, A. Vander Meersech, Tooting. *etc.* P. H. Jones.
TURKEYS.—1, G. H. Gregory, Taunton. 2 and *etc.* P. H. Jones. *c.* A. Vander Meersech.
ANY OTHER DISTINCT VARIETY.—1, F. Chambers, Northampton (White Owls). 2, P. H. Jones, Fulham, London. *etc.* P. H. Jones, A. & W. H. Silvester. *Ac.* C. Gamon, G. H. Gregory.
SELLING CLASS.—1 and *Ac.* J. F. Rackham (Carriers and Barbs). 2, A. Vander Meersech. *etc.* C. Norman.

The Judges were Messrs. Percival and Hutton.

WIGTOWNSHIRE SHOW OF POULTRY, &c.

This was held on the 8rd inst. in the Queen's Hall, Stranraer. The pens were of wood, with wire fronts; the entries being uncommonly good for so out-of-way place—viz., something like five hundred in all. The prizes were small, but there were several extras given in the shape of plate and useful articles of cutlery.

Spanish were first on the list, and these were a grand class, old birds winning the prizes. *Silver-Gray Dorkings* were (as usual on the west coast of Scotland) superior, and the winners good; but *Dark Greys* were better, the cup going to a substantial pair of that variety. *Brahmas* were very good, and all *Dark Birds*; the first, a fine massive pen, won also the extra. In *Cochins* there were some grand hens, all Buffs, and one grand cock in the first-prize pen. *Game*, *Black Reds*, were very good, some of the hens being of the highest quality; but the cup was awarded to a sound-coloured pen of *Duckings*. *Game Bantams*, *Reds*, were not good, and the variety class only moderate; the first *Silver Sebrights*, second *Pile Game*, and third *Gold Sebrights*. *Hamburghs* were a fine lot, the winners leaving little to be desired; the first in *Silver-pencils* won also the cup for the section and the cup for the best pen in the Show. *Houdans* were pretty good, but the best had the *Crève comb*; a fair pen of chickens coming second with the lowest style of comb. In the Variety class first were *Silver Polands*, second *Malays*, and third *Scotch Greys*, all very good of their kind. *Ducks*.—Only the winners of *Aylesbury* were of note, but they were very good; the *Rouens* were very good, the first large and very well pencilled. With the exception of the first in *Selling class* (*Silver-spangles*) there was nothing good. *Turkeys* and *Geese* small, but otherwise good.

Pigeons were shown in pairs, and the pens too small for the purpose, especially those for *Fantails* and *Pouters*. In the last-named the first and second were *Blue-pied*, and third *White*; a good pair of *Mealies* very highly commended. *Carriers* were pretty good, and the winners *Blacks*. *Tumblers* were good, *Agates* winning first and second, and third *Long-faced Black Moties*. *Fantails* were very good in both style and carriage. *Jacobins* good as regards the winners. *Nuns* and *Barbs* good, but the latter young. *Magpies* were moderate, and the winners *Black*; but the crack pen of the Show was a pair of *White-barred Red Swiss* in the Variety class. A class was provided for common *Pigeons*, the first going to a pair of *Blue Chequers* of very original type of head.

In a recent number of one of your contemporaries our awards in this class were rudely criticised without once attempting to set us right as to the type of bird required in Scotland, but we think it would be as well for the writer to give us a standard before attempting to lecture those who assisted in the settlement of this style of bird more than a dozen years ago.

There was a good show of *Cage Birds*, especially in *Goldfinches* and foreign varieties.

SPARKIES.—1, 2, and *etc.* W. Martin, Stranraer. 2, J. Ross, Lochans Mills. *Ac.* W. Martin, J. Ross, W. Withers.
DORKINGS.—*Silver-Gray*.—1, G. W. Congreve, Carlisle, Castle Douglas. 2, W. Martin. 3, A. Withers. *Ac.* G. W. Congreve, A. M'Dowall, Anstruther. *Any other colour*.—1, W. Martin. 2, R. Reed, Hollinhurst. 3, A. Mather, Kilmarnock. *Ac.* R. Reed, A. Withers, R. V. A. Adair, Giltoun.

BRAHMA POULTRY.—1 and 2, W. Martin. 3, P. M'Lean, Duchra. *Ac.* A. Withers, A. Hutchinson. *c.* R. Maxwell, Dumfries (3).

COCHIN-CHINAS.—1, W. Martin. 2 and *Ac.* Hutchinson. 3, Miss E. A. Knott, Dumfries. *Ac.* A. Withers. *c.* W. Martin, J. M'Lealand, Lochans.

GAME.—*Black and other Reds*.—1, W. Martin. 2 and 3, T. Parker, Southwick Station. *Ac.* W. Martin (2), J. A. Mather, Closeburn (3). *c.* M. Marshall, Drumore. *Duckings*, *Whites*, and *other Greys*.—1, J. A. Mather. 2, T. Kennedy, Dumfries. 3, W. Martin. *c.* W. Carson, Glenluce.

GAME BANTAMS.—*Black and other Reds*.—Cup, A. Withers. 1, Miss M. Moore, Glenluce. 2, W. Martin. 3 and *Ac.* W. Martin, W. M'Clure, Lochan Mills; J. Carroll, Lochmaben; D. M'Caughie, Pollockshaws.

BANTAMS.—*Any other variety*.—1, A. Hutchinson. 2 and 3, W. Martin. *etc.* W. Murray, Hexham. *Ac.* W. Martin (3), D. M'Lealand, W. Martin, W. Geddes, Dalbeattie; A. Firth, Whitecroft, Belfast, W. Murray.

HAMBURGH.—*Golden-spangled*.—1, W. Martin. 2, W. M'Clure. 3, S. Bone, Lochans. *c.* R. Reed. *Silver-spangled*.—1, 2, and *etc.* W. Martin. 3 and *Ac.* P. M'Lean. *c.* W. Cumming, Kirkcubbin; J. M'Harrie, Culhorn Mains; J. Ross.

HAMBURGH.—*Golden-pencilled*.—1 and 2, W. Martin. 3, J. Ross. *Ac.* D. Blair, J. Aitken. *c.* G. M'Dowall, J. Dorans, Stranraer; J. Sicular. *Silver-pencilled*.—1 and *etc.* W. Martin. 2 and 3, J. M'Dowall, Anstruther. 3, W. Reddihough, Kilmarnock, Co. L. *Ac.* W. Martin, J. Spens, Low Ardwell.

HAMBROUS.—*Black*.—1, J. Ross. 2 and 3, W. Martin. *Ac.* J. Ross, J. Craig. *c.* W. Peebles, J. Graham, *etc.* Carlisle.

HOUDANS.—1, W. Martin. 2, Mrs. M. Carter, Port Carlisle. 3, A. Withers. *Ac.* P. Allinson, Holmrook. *c.* J. Robinson, Cleendrie; Miss Robertson.

ANY OTHER VARIETY.—1, W. Martin. 2, A. Yeudall, Galston. 3, A. Hamilton, Carlisle. *Ac.* A. Withers, Miss E. A. Knott, W. Hartley, Earby.

DUCKS.—*Aylesbury*.—1, F. Robinson, Belfast. 2, R. V. A. Adair. 3 and *Ac.* W. Martin. *Rouens*.—1, *etc.* and *Ac.* W. Martin. 2, F. Robertson. 3, G. M'Dowall.

ANY OTHER VARIETY.—1 and 2, W. Martin. 3, A. Hutchinson. *Ac.* W. Martin, G. W. Congreve.

SELLING CLASS.—2, G. M'Dowall, A. Hutchinson. *etc.* A. M'Harrie. *Ac.* W. Martin (2), G. W. Congreve, P. M'Lean, A. Hutchinson, J. Fisher, Stranraer. *c.* W. Martin.

TURKEYS.—1, W. Martin. 2, J. Spens.

GEES.—1, J. Spens. 2 and 3, W. Martin.

PIGEONS.

POUTERS.—1, J. & P. Thorburn, Stranraer. 2, 3, and *Ac.* A. Hutchinson. *LETTER CARRIERS*.—1, 2, 3, and *Ac.* A. Hutchinson. *c.* W. Martin.

TUMBLERS.—1, 2, 3, and *Ac.* A. Hutchinson. *c.* J. Ross, Newton-Stewart; W. Martin.

FANTAILS.—1 and 2, J. Waters, Belfast. 3, A. Hutchinson. *c.* Miss E. A. Knott, A. Hutchinson.

JACOBIANS.—1, 2, *Ac.* and *c.* A. Hutchinson. 3, J. Gilmour, jun., Galston.

NUNS.—1 and 2, A. Hutchinson. 3, D. M'Arthur, Newton-Stewart.

BARBS.—1, 2, and 3, A. Hutchinson. *c.* T. Maxwell, Maxwelltown, Dumfries.

TURKEYS.—1, 2, 3, and *c.* A. Hutchinson.

ANTWERPS.—1, 2, and 3, A. Hutchinson.

BALDS OR BEARDS.—1 and 2, A. Hutchinson. 3, W. Martin. *Ac.* W. Martin, J. Gilmour, jun. *c.* W. Martin (3), J. Ralston, jun., Stranraer.

MAGPIES.—1 and 2, A. Hutchinson. 3, J. Gilmour, jun. *Ac.* J. & W. Towerson, Egmont.

COCHINS.—1, W. Martin. 2 and 3, A. Hutchinson.

ANY OTHER VARIETY.—1, 2, *Ac.* and *c.* A. Hutchinson. 3, W. Martin.

SELLING CLASS.—1, 2, 3, and *Ac.* A. Hutchinson.

CAGE BIRDS.

CLEAN YELLOW.—*Cock*.—1, P. Watson, Girvan. 2 and 3, A. Hutchinson. *Hen*.—1 and 2, W. Martin. 3, J. M'Creddie, Stranraer.

CLEAN BUFF.—*Cock*.—1 and 2, W. Martin. *Hen*.—1, 2, and 3, A. Hutchinson.

YELLOW PIRNALL.—*Cock*.—1, A. Hutchinson. 2, R. Bisset. 3, A. M'Dowall.

Hen.—1, J. M'Creddie. 2 and 3, W. Martin.

BUFF PIRNALL.—*Cock*.—1, W. Martin. 2 and 3, J. M'Creddie. *Hen*.—1, A. Hutchinson. 2, W. Martin. 3, J. M'Creddie.

GOLDFINCH MULE.—1, 2, and 3, A. Hutchinson.

GOLDFINCH.—1, A. M'Kelso, Stranraer; W. Martin. 2, J. Mackie, Ernespie.

Ac. R. Baines, Ligoniel, Belfast. *c.* W. S. Lawson, Girvan.

SELLING CLASS.—1, A. Hutchinson. 2, W. Martin.

FARROT OR OTHER FOREIGN BIRD.—1 and 2, W. Martin. 3, J. Calderwood, Droughdool.

JUDGES.—*Poultry and Pigeons*: Mr. E. Hutton, Pudsey, Leeds.

Cage Birds: Mr. T. Scott, Carlisle.

FORFAR SHOW OF POULTRY, &c.

This large Show was held in the Reid Hall, Forfar, on December 31st and January 1st, and in point both of quality and numbers far exceeded any of the Association's previous exhibitions.

As usual *Game* were the principal feature of the Show, there being no less than 105 entries of them alone. There were twenty-nine *Black Red* cocks exhibited, and many a good bird had to put up with a commendation. First was a very stylish cockerel, though rather on the small scale; second a good bird; while third was about best in the class, but had met with an accident and had the most of his tail knocked out. *Black Red* hens formed one of the best classes in the Show. First, a grand one, well deserved her place. Second we did not so much like, had not such a nice head as a number of others; but of course it might be that the others did not handle so well. *Brown Red* cocks were headed by about the best *Game* cock in the Show; splendid colour and very hard, and looked a *Game* bird all over. Second was a very stylish bird, and these two were very easy winners. *Brown Red* hens a fair class, but not up to the *Black Reds*. Cocks of any other colour were well represented. First was a fine *Pile* with a good *Duckwing* second, and were well placed. In hens of any other colour an excellent *Duckwing* won. *Game Bantams* had two classes for cocks—viz., *Black Red* and *Any other colour*. In the former a nice *Black Red* won. Second also fine; but we did not care much for the third, and would have put 107, highly commended (*Donald*) or 112, highly commended (*Walker*) in that position. In the next class Mr. Brownlie easily won with one of his grand *Piles*, beating the *Black Red* for the cup. Second also a good *Pile*, while a *Brown Red* was third. Hens of any colour, we did not like the judging at all. First was a *Brown Red*, good for its colour, but a poor thing beside Mr. Brownlie's grand *Pile*. Second was right, but 137 (*Shield*), highly commended, should have been third. In *Any other variety* Mr. Ashton's well-known *Blacks* won. *Hamburghs* were very numerous and good, especially *Pencilled* hens; while *Dorkings* were fairly up to the usual run at this Show, Mr. Gellatly's and Mr. Armitstead's well-known birds coming to the front. *Brahma* cocks were fairly well represented, while hens of the same were very good, first going to a good-coloured, finely pencilled bird. All the prizes in *Cochin* cocks went to *Partridge*, and in hens to *Bluffs*. *Spanish* were an exceeding fine lot, the cup-winner in the hens being of grand quality. In the Variety class (cocks) first and second went to *Golden Polands*, third *Black Hamburgh*; and in hens to *Poland*.

Pigeons were a great advance on former years owing to increased prize money and extended classification. *Pouter* cocks

the, J. Wyse. ac, F. C. Parker, J. Dargie, J. Pantom, c, J. Bunole. Hen.—1, Mrs. A. G. Dunham, 2, J. Fowles, 3, Mrs. Oswald, ac, A. Dryburgh, A. Bowie. c, Earl of Roslyn.

HEXHAM SHOW OF POULTRY, &c.

This was held at Hexham, in the Town Hall and Corn Exchange, on New Year's Day. On account of some losses the prize list had been to some extent curtailed, many classes of poultry and Pigeons with Rabbits and Cats being dispensed with, but withal the entries were good. The Show was well managed, the pens were from Stoke-on-Trent, and the birds well provided for as regards food and water.

Brahmas were pretty good, the first large and well marked, the second hen even better than the first, but the cock not near so good. **Cochins**, the winners superb. First and second Buffs, third Partridge. The first-named also winning the cup for the section. **Dorkings** were poor. **Game** (Red), were a heavy class, the first and third Brown, and second Black-breasted Red; but the cup for Game was won by one of the best Duckwing cockerels ever seen, both as regards colour and shape. **Bantams** as usual were a grand section, the cup being awarded to a pen of Black Reds of fine quality and in the pink of condition, many other pens proving almost equal. In the next class Piles were first, and Duckwings second and third. **Game Bantam** cocks were very good, the first and third going to Black, and second to Brown-breasted Red. In the following class Black and Silver Sebrights won. **Spanish** a small but good lot, and mostly old birds. The cup for this section, however, going to a grand pen. **Hamburgs.**—In Pencils the birds were poor with the exception of the first-prize Golden. In the Variety class the first and cup were won by Golden Polands, the second Black Hamburgs, and third Crève-Cœurs. There was but one class for **Ducks**, the winners being Rouens and Spotted Bills.

A capital class. The Selling class contained some cheap lots, and many pens changed hands. In the local class for the large varieties were some capital birds, especially the Cochins and Spanish, but the best of these were the Bantams, which were almost equal to the open classes in point of merit.

Pigeons made a capital display, the Pouters being placed in some capital pens showed to great advantage and were a show in themselves. Carriers were not equal to the Pouters as classes, but we recognised some good birds among the lot in all the classes, the winners being Blacks and Duns in all cases. In Short-faced Tumblers were some good birds, not alone in head properties, but also in colour and marking, Almonds being to the front. Barbs were a fair lot and mostly young birds. Dragons were a large good class, the first a Blue, and second and third Silvers. All birds of the right stamp. In Dragons, any other colour, the first was a Red, second Yellow, and third a Grizzle, the two first right grand birds in every respect. Short-faced Antwerps were poor as a class, and only the first in Long-faces deserves a notice, but this, a Red Chequer, was particularly good. Turbits had two classes, and these were about the best classes in the Show. English Owls were not good, many being far too straight in beak, but the colour and frill in most cases were very good. Fantails very good and well placed, while in Jacobins also there were some good birds, notably the cup Red, and Messrs. Brydone and Alderson's Yellows. Magpies and Nuns were in one lot and very good, while Long-faced Tumblers were divided. In the second of these Almonds won, but some of these too nearly approached their Short-faced brethren.

Cage Birds were a small but select lot, among which we recognised some of the champions of this season—notably the four-pointed Linnet Mule shown by Mr. Spence, and to which was awarded the cup for the best in the Show.

Brahmas.—1, R. Shield, Swallow, 2, Dr. Holmes, Whitecoats, 3, S. Teasdale, Alston. *ac, C. Venables, J. Benn, T. Webb, Mrs. A. Ellison.*

Cochins.—Cup, 1, and 2, G. H. Proctor, Durham, 3, J. Bell, Linnels. *c, Henderson & Close.*

Dorkings.—1 and 2, J. Wardle, West Wylen, 3, J. Coulson, Shetley Bridge, *Game.*—*Black and Red.*—1, W. Youngusband, Darlington, 2, J. Brough, Carls, 3, C. Venables. *ac, T. Young, W. Youngusband, W. Ormerod, Miss Nelson.* *Any other colour.*—Cup and 1, Miss Nelson, Cuckshaw, 2, G. Holmes, Driffield, 3 and c, W. Drydale, Morpeth. *ac, T. Grierson, T. Young, L. A. and H. H. Staveley, G. Rutherford.*

GAME BANTAMS.—*Black or Brown Reds.*—Cup and 1, R. White, Cuckshaw, 2, W. Wardle, 3, C. Miller, Southwick. *the, T. Gothard. ac, W. Wardle, T. Dewell, W. Murray. c, R. Wood, J. Wilson.*

ANY OTHER VARIETY.—Cup and 1, J. Bellingham & Gill, 2, T. Dowell, 3, G. Ridley, c, J. Cook, J. Burnip, R. White, J. A. Davis, G. Coulthard. **GAME BANTAMS.**—*Cock*—1, J. Nelson, 2, R. English, 3, J. Cook, ac, W. Wardle, T. Gothard, R. Shield, J. Purvis. *c, T. Dowell, G. Coulthard.*

BANTAMS.—*Not Game*—1, R. H. Ashton, 2, T. H. Cartwright, 3, T. P. Carver, ac, G. Holmes, Miss M. J. Nelson, T. H. Cartwright, c, J. Judson, c, W. Newbegg, T. H. Cartwright.

SPANISH.—1 and 2, Willoughby & Purvis, 3, H. Wilkinson. *ac, J. Richardson, c, R. Sewell.*

JUDGES.—*Poultry:* Mr. Hutton, Pudsey. *Pigeons:* Mr. Rule, Durham. *Cage Birds:* Mr. Blakston, Sunderland.

BAILDON ORNITHOLOGICAL AND COLUMBARIAN SOCIETY.

THE annual Exhibition of the above Society was held in the large room of the Church of England Schools, Baildon, on the 7th and 8th inst. In point of entries there was a falling-off in both the Pigeon and Cage-bird classes of nearly 200 compared with last year's show, still the general quality of the birds was good, particularly in the Cage-bird portion. The new Secretary Mr. Hutton, considering he was new in the cause, worked through the business tolerably well. There was but one slight hitch in the Show worth recording, that of a couple of Pigeons having been wrongly penned, which for a time caused a little difficulty both to the respective exhibitors, Judge, and Committee, and we think the easiest way to have overcome the difficulty would have been for the Committee to have allowed an extra prize to have been awarded. We may likewise draw attention to the schedule, which needs some revision for another show. We think Carriers or Pouters should head the list instead of Jacobins. The classes throughout were fairly represented, Antwerps taking the lead with about eighty-three birds in the six classes. There were two classes for English Owls and none for Foreign, and but one class for Tumblers—that of Long-faced.

In the Canary section we noticed an entire absence of the Norwich birds, which had been struck out of the schedule; for what particular reason we know not, unless the pepper question is already beginning to deter some of the fanciers who really cannot keep pace with the enormous expense in moulting them, and even then with but slight chance of winning. We would advise the Committee another year to reinstate the classes, and offer premiums to birds not moulted with pepper. There were a few good Belgians (especially the first and second prizes), and Coppies and Plain-heads; but a great feature in the Exhibition was the Yorkshire-bred birds, some of which were splendidly marked. The classes for British Birds were attractive and exceedingly interesting, and we noticed that the White Black-bird achieved another laurel to the several already won. By-the-by there was a Nightingale in the Show, but it had a feather in its tail—a somewhat uncommon occurrence, and being one feather more than the four Nightingales could muster at the recent Hanley Show. The awards of Mr. Calvert of York was tolerably good all round; but still this was not the best part of the proceedings, for the worthy hostess of the "Malt Shovel" provided for the Judges, Committee, and reporters a dinner fit for a king to partake of.

PIGEONS.

DRACONS.—*Cock or Hen.*—1, Clayton & Bairstow. 2, F. W. Jennings. 3, Ward & Rhodes. *etc.*, E. Horner. *Ac.* V. Ratcliffe, J. Mann, E. Mawson.

TURKISH.—*Cock or Hen.*—1 and *etc.*, E. Horner. 2, W. Wilkin. 3, S. Dewhurst. *etc.*, J. Moor.

LONG-FACED TUMBLERS.—*Cock or Hen.*—1, A. Hawley. 2, J. Cargill. 3, W. Lund. *Ac.* E. Mawson, Garbutt & Sldgwick.

BARBS.—*Cock or Hen.*—1, E. Mawson. 2, E. Horner. 3, J. Thresh.

ANY OTHER VARIETY.—1, A. Hawley. 2, B. Rawnsley. 3, E. Horner. *Ac.* G. W. Holloway, W. Wilkin.

SELLING CLASS.—1, E. C. Stretch. 2, W. Ellis. 3, E. Horner. *etc.*, W. A. Newall, Jagger & Hartley, E. Mawson, A. Hawley, B. Rawnsley. *c.* Tordoff and Wilkin.

CAGE BIRDS.

BELGIAN.—*Yellow or Buff, Clear or Ticked.*—1 and 2, Cleminson & Ellerton.

Ac. W. Shackleton. *c.* R. Barrett.

COFFY.—*Yellow, Clear or Grey Crest.*—1, O. Paley. 2, R. Usher. 3, W. Lancaster. *Ac.* J. Balstrick. *Buff, Clear or Grey Crest.*—1, J. & H. Garbutt. 2, R. Simpson. 3, P. Rawnsley. *Ac.* L. Belk. *Plata-headed, Yellow or Buff, Clear or Ticked.*—1, R. Simpson. 2, J. & H. Garbutt. 3 and *Ac.*, G. A. Watson.

LIZARDS.—*Golden-spangled.*—1, J. Stevens. 2, Cleminson & Ellerton. *Silver-spangled.*—1, J. Stevens. 2, O. Paley. 3, Miss Wells. *Ac.* Cleminson and Ellerton.

YORKSHIRE.—*Clear Yellow.*—1, W. Lancaster. 2, J. Overend. 3, J. & H. Garbutt. *Ac.* G. A. Watson. *Clear Buff.*—1, W. Lancaster. 2, J. Thackrey. 3, G. Turner. *Ac.* J. Overend.

YORKSHIRE.—*Evenly-marked Yellow.*—1 and 2, J. Thackrey. *Ac.* L. Belk. *Evenly-marked Buff.*—1 and 2, J. Thackrey. 3, L. Belk. *Ac.* P. Rawnsley.

YORKSHIRE.—*Ticked or Unevenly-marked Yellow.*—1, J. Overend. 2, Fawcett and Anderson. 3, J. Thackrey. *Ac.* R. Pearson. *Ticked or Unevenly-marked Buff.*—1, J. Thackrey. 2 and 3, G. Turner. *Ac.* J. & H. Garbutt.

CINNAMON.—*Buff or Jonque.*—1, J. W. Howitt. 2, C. Worth. 3, Fawcett and Anderson. *Marked or Variegated.*—1, T. Tennisswood. 2, W. & C. Burniston.

Ac. P. Rawnsley. *Ac.* L. Belk.

GOLDFINGER MULES.—*Clear or Variegated.*—1, Barr & Young. 2 and 3, J. Stevens. *etc.* and *Ac.*, Stroude & Goode. *Dark.*—1 and 2, W. Lancaster. 3, G. A. Watson.

LINNET AND CANARY MULES.—1 and 2, J. Stevens. 3, R. Simpson. *etc.*, W. Lancaster.

MULES.—*Any other variety.*—1, J. Stevens. 2, W. Lancaster. 3, Stroude and Goode.

GOLDFINGERS.—1, Cleminson & Ellerton. 2, W. Lancaster. 3, J. Pearson. *etc.*, T. Foster.

BULFINCHES.—1 and 2, J. Rowland. 3, R. Barrett. *Ac.* C. Worth.

BROWN LINNETS.—1, W. H. Batchelor. 2, R. Pearson. 3, W. Carrick. *etc.*, R. Pearson.

ANY OTHER VARIETY.—1, J. Hall. 1 and special, R. Humphrey. 2, W. & C. Burniston. 3 and special, J. Hutton. 3, W. Bastow. *etc.*, J. Whitaker.

SELLING CLASS.—1, J. W. Howitt. 2, J. Ellis. 3, Fawcett & Anderson. *Ac.*, W. Bastow.

JUDGES.—*Pigeons,* Mr. J. Thompson, Bingley. *Canaries,* Mr. J. Calvert, York.

REIGATE SHOW OF POULTRY, &c.

THIS Show was held on the 5th and 6th inst. at the Drill Hall, a capital building for the purpose, but rather inconveniently situated.

The management was good and the classes for poultry and Rabbits were well filled. The Pigeon prize list was a liberal one, but it was not so well supported. *Dorkings.*—In coloured cocks the first and second were good birds, rest moderate. *Hens.*—First (Parlett), a grand specimen. Second and third deserved their position. This was a capital class. Any other colour.—First (Blue), rich in colour, of fair size, but rather coarse in comb. Second (Blue), a neat bird, but not so large as the winner. Third a moderate White. *Hens.*—First (Crosswell), a beautiful White. Second a handsome Cuckoo. Third, a Cuckoo, not quite so good in colour. *Cochins, cocks.*—First (Lingwood), a fine bird. Third (Christy), we liked better than the second. He had many good points and was better in colour. *Hens.*—Mr. Bloodworth and Mr. Darby exhibited two good old birds. Mrs. Christy also showed a fine coloured pullet, commended. Any other colour, Capt. Talbot won in both classes with superb Whites. *Brahmas.*—First (Lingwood), a fine old bird, the rest only moderate. *Hens.*—A better class, Rev. J. D. Peake winning with a beautifully pencilled bird. Second was well marked but wanted leg feather. *Lights.*—Good classes. First (Haines), a grand bird. Second (Lingwood), also a fine specimen. *Hens.*—A nice class, Capt. Savile winning with a bird of very pure colour and well marked in the hackle. *Spanish.*—Eleven entries, nearly all good, Mr. A. Hewes winning the cup with birds of fine quality but a little out of condition. *Game* classes were satisfactory. The cup was secured by a fine Brown hen of good style. Any other variety class obtained only three entries. The pen of Piles that was awarded first would have maintained its position in a much larger competition. *Houdan* classes were very good. In the *French* we preferred the second-prize pen to the winners. *Hamburghs* were moderate classes, Mr. Long's birds arrived too late for competition. In the class for *Leghorns* a pretty pen of Whites was first. *Game Bantams, Black Reds.*—First and cup (Anns), a nice coloured pen, but for style and closeness of feather we preferred the second. Any other variety.—First (Marsh), Duckwings, a really handsome pen. *Ducks, Geese, and Turkeys* all obtained good entries, and the selections were well made.

Pigeons.—Pouters only seven entries in the two classes. Carriers were much better supported. In cocks Mr. Cucksey was first with a grand bird, fine in eye and wattle, and shown in good condition. He also exhibited a bird of great promise in the young class. Tumblers were small classes, but a few handsome birds were to be found, the most noticeable being Mr. Fulton's Almond cock, and the Almond and Agate hens of Mr. Jayne. Messrs. Loversidge and Maynard exhibited some beautiful Fantails, and Mr. Fulton a rare pair of Trumpeters. The rest called for no special comment.

Messrs. Leno and Nichols judged the poultry, and Mr. Corker the Pigeons.

[We have a letter from "A SURREY PARSON" pointing out

defects which require remedy at future shows. This will be in our columns next week.—Eds.]

POOLE POULTRY SHOW.

WITH the new year another Dorsetshire town makes its *début* in the poultry-show world. We are glad of it, for exhibitions are needed in that county, that part of the world not coming off so richly as the midland and northern counties. For the first Show it may be called a great success. We should think many of the pens came on from Bristol, and wonder Reigate with its more numerous and substantial prizes did not catch all the travellers. At Poole we found 221 pens of poultry and 185 pens of Pigeons, and the quality was exceedingly good. Mr. Tegetmeier awarded the prizes, and seemed to give satisfaction. The Committee were courteous, and took every possible pains for the well-being of the Show. We should recommend them, however, next time to announce who their Judge is to be. We know on this occasion ignorance on this point kept one or two from exhibiting. It is now nearly always done, and the results show the well-working of the system.

Brahmas came first; the two colours made up no less than forty-one pens. The Darks were good, and the first-prize pen of Lights really admirable. One or two more pens of this colour were deserving of a prize, but there were none for them. We are convinced third prizes are of the greatest value not only to the Committee and exhibitors, but to a judge, for it is a very difficult business to select a couple of pens out of, perhaps, half a dozen of nearly equal merit. *Cochins* were capital. The winners were a nice pen, and cheap at catalogue price of £3 3s. A good pair of adults were second, fair in colour. In the next class good Whites were first, the cock a very good bird; second went to neat Partridge. This was a wonderfully good class. *Dorkings* of all colours met together, and the result was, of course, that Silver-Greys and Whites were not to be found. A pair of old birds were first, and we think properly so. *Houdans* again were a good class, and on the whole the colour was, perhaps, more even throughout. We are glad to note of late, too, an improvement in the combs of this variety. Mr. Chisman's two pens were only in at 50s. and 30s., and must have speedily found purchasers. In the other *French* class *Crêves* won all the prizes. All the noticed birds were adults. The prize pens were large and good in shape. 85 (Sturt) had a nice cock, and we liked the hen in Mr. Vickery's pen. *Game* had only one class, and consequently only five pens were entered. These were, however, very fair, and the winners would have come out well in larger competition. Pencilled *Hamburgs* were wretched, and only a second prize was awarded. Spangled were better, and made quite a neat little show. *Polish* were wonderfully good, and an extra first was awarded here, and deservedly so. The White-crested Blacks were a long way above the average, and justify our remarks made from time to time that the breed is rapidly looking-up. It is now time for secretaries to take their turn and give now and then a class for this variety, and so yet more push on the cultivation of this one of the most striking breeds we have. Mr. Hinton's Silvers were capital, being good in crest and markings. In the Variety class Malays won all the prizes, and a good pen of the same breed (White) was commended. *Game Bantams* were many in numbers, but the preponderance were too large and heavy. In the next class *Sebrights* were first, second going to Blacks. Mr. Bloodworth showed a pretty pair of White Rose-combs, and Mr. Dugmore sent some fair White Booteds. *Ducks* had only one class, where Rouens and Aylesburys won the prizes. It is a mistake to have such general classes, and no one ought to support them. The *Sale* classes were large and fairly good; there were sixty pens in the two receptacles. The first-prize *Hamburgh* cock was capital, second going to a cheap *Brahma* at 25s.

The *Pigeons* were very good, some of the classes being unusually so. In the ten pens of *Carriers*, however, which were entered the Judge only found two pens up to the prize standard. *Pouters*, however, were better, and Mr. Holloway won with a good long bird. *Tumblers* were numerous and good. Messrs. Powell & Crane and Mr. Andrews entering ten pens between them. It was amusing to notice how many strings many had to their bows. We suppose they had designs on Sir Ivor Guest's point cup. *Dragoons* were a good class. The first-prize bird soon, we hear, found a new home for £5. *Fantails* were wonderfully good. It must have been a difficult job to choose the winners, for the Judge could easily have bestowed half a dozen prizes. After the winners we liked Mr. Loversidge's two pens and Mr. Hinton's. *Jacobins* again were capital, and here Mr. Andrews entered half a score of birds. Had there been no point cup he, perhaps, would have entered two. *Turbits* were neat, and nearly every pen was noticed. *Antwerps* were a capital class, and the Judge seemed to be quite at home among them; he had plenty of work, however, for many pens were very even in quality. The Variety class was very interesting. A *Sale* class (pairs) followed of fair quality, and a class for *Blue Dragoons*, apparently an after-thought, finished-up the catalogue,

where Messrs. Andrews and Shutler each had four pens, their final effort, perhaps, for the points cup; it was, however, won by the former gentleman, the latter having first, we believe, in the borough prizes for the best single Pigeon; while Mr. Gollop won first for the best pen in the poultry classes open to the borough. We furnish full awards below.

Brahmas.—Dark.—1. Lays. 2. H. R. Dugmore. c. Mrs. Radclyffe, G. Huey, Light.—1 and 2. Mrs. T. Turner. 3. W. Young. c. G. Jennings. — Chisman. — Bloodworth.
Cochins.—Buff.—1. J. Ogilvie. 2. Mrs. Radclyffe. vhc. Mrs. O. T. Parke. Any other variety.—1. Bloodworth. 2. Mrs. Radclyffe. hc. G. Clarke. — Lays, G. Lias. c. F. C. Bentinck, J. Allen, jun.
Dorkings.—1. Mrs. Radclyffe. 2. — Bentinck. hc. Mrs. Pope. c. — Chisman, T. Rawlins.
Houdans.—1. — Chisman. 2. F. Holmes. hc. — Parten, J. Allen. c. — Elford. — Lays. — Chisman. — Bishop.
Polishes.—1. — Bentinck. 2. Rev. J. H. Ward. hc. — Vickery. — Huey. — Sturt.
Game.—1. — Farquharson. 2. C. Martin. hc. H. Stagg. c. F. Lewington. *Hamburgs*.—Pencilled.—2. J. Dibben. Spangled.—1. — Gollop. 2. — Boswell. c. F. A. Davis, J. K. Harris.
Polishes.—Extra 1. T. P. Edwards. 1. J. Hinton. 2. G. Lias. hc. T. P. Edwards. — Bloodworth.
Spanish.—1. J. Chisman. 2. C. Parmiter.
Any other variety.—1. J. Hinton. 2. S. B. Perry. hc. H. R. Dugmore. c. G. White.
Game Bantams.—1. Mrs. Farquharson. 2. — Hookaday. c. — Gollop. — Young. — Jennings. — Hardy. — Vickery, Coon Brothers. — Huey. — Young.
Bantams.—Any other variety.—1. C. H. Poole. 2. — Ashton. hc. — Bloodworth, H. B. Dugmore. c. H. R. Dugmore.
Ducks.—1 and 2. Mrs. Radclyffe. hc. B. Oakes. — Martin, F. T. Rogers. c. W. R. Fryer, H. R. Dugmore.
Selling Class.—Cock.—1. G. Pettis. 2. B. A. Hogg. hc. — Bentinck, T. P. Edwards. — Parmiter, Mrs. Parke. — Caws, W. Norman. G. White, P. Ogilvie. c. Mrs. T. Turner. Hen.—1. J. Bloodworth. 2. W. D. Dugdale. vhc. — Bentinck, W. D. Dugdale. hc. G. Clarke. — Radclyffe, T. P. Edwards, Mrs. T. Turner. — Bentinck, C. J. Woodford. c. — Whitehead.

PIGEONS.

Carriers.—1. W. Morris. 2. W. Turner.
Pouters.—1. G. Holloway. 2 and 3. — Hicks. hc. — Harker.
Tumblers.—1. Powell & Crane. 2. J. Andrews. hc. J. Blackman, Powell and Crane, J. Andrews. c. C. Hurdle.
Fantails.—1. Walker. 2. — Andrews. hc. — Walker. — Holloway.
Loversidge. — Hinton, W. Morris. c. — Munt. — Parsons, W. Morris.
Jacobins.—1 and 2. J. Andrews. hc. J. Andrews. — Phelps. — Morris.
Turbits. — 1. — Washbourne. 2. — Maurice. vhc. H. Bolt. — Crafer, W. Young. C. Parsons. — Washbourne.
Antwerps.—1. Powell & Crane. 2. — Young. hc. G. Harris. — Fitz-Herbert, G. H. Billeit, Powell & Crane, W. D. Richardson, C. J. Woodford.
Any variety.—1. Powell & Crane. 2. — Barnard. hc. O. C. Farrer. — Dunman, J. P. Mills. — Washbourne, R. Wilkinson. c. — Farrer. — Dunman.
Selling Class.—1. J. Andrews. 2. — Young. hc. G. Holloway, J. Andrews. C. Hurdle. c. — Mann. — Harker. c. Hurdle.
Dragoons.—1. — Lush. 2. R. Shutler. hc. Powell & Crane, R. Shutler, C. A. Pearson, W. Turner. c. — Pearson. Blue.—1, 2, and 3. — Shutler. vhc. Powell and Crane, J. Andrews. c. J. Andrews.

BOROUGH PRIZES.

Poultry Cup.—H. R. Dugmore. 1. G. Gollop. 2. F. Holmes. 3. W. Young.
Pigeon Cup.—J. Andrews. 1 and 2. R. Shutler. 3. J. Andrews.
JUDGE.—Mr. W. B. Tegetmeier.

ULVERSTON SHOW OF POULTRY, &c.

For some years there has been no Show of poultry at Ulverston, but this year it has been revived with good effect, a grand exhibition of poultry and cage birds being the result. The Music Hall proved too small for the number of entries, which were about five hundred, and many of the pens had to be placed on the ground rising three tiers high, the room between being limited; the day was a wretched one for light, so that in many cases judging was little more than guesswork, and in others a paraffin lamp was brought into requisition. This is almost entirely a country of *Game* fanciers, and nowhere do we find the *Game* fowl in so high a state of cultivation or so thoroughly understood, and the exhibits are almost to a lot the produce of the locality, and not merely a lot of birds brought together by £ s. d. only, and we have no hesitation in saying there has been no such display of this variety at any other show this season. In some of the classes a dozen birds might have been removed and then have left worthy recipients of the cups and prizes. In both single cocks and cockerels were birds of the highest merit, the competition being very close in both cases. Brown Reds were first and third, and Black Reds second. Of Red pullets there were eighteen, but we will not venture the assertion that these were well placed, although three good birds won the prizes, but this class occupied about the worst position in the Show. In cockerels any other colour, first and third were Duckwings, and second the best Blacks we have seen for the last dozen years. The pullets were Piles and Duckwings, and a very good class. *Cochins* were good in all classes of Buffs, the winners grand in all points. The Variety class cocks were first and third Partridge, second White. The first and cup for *Cochins* going to a Partridge hen, which it would be incorrect to say was better than the first-prize Buff, which is about perfect; but in her own class she is a marvel. *Brahmas* large classes and all the winners Dark, the Light birds poor. The quality of these classes was a surprise to us, the hen taking the plate over the cock. This is a splendid-styled bird, combining all the grand points of colour and marking. *French* a fair class, and the cup won by La Flèche. *Spanish* and *Dorkings* were but poor in both numbers and quality as compared with the foregoing. In *Hamburgs* were some good

When first a direct commerce between Morlaix and England was opened in 1851 by a steamboat called the "Grand Turk,"

from Southampton, lots of eggs were sent over from Brittany for sale. But these little Breton eggs were smaller than the ring-maker had ever thought possible, for they all went easily through the smallest ring, and of course, fetched only the smallest price. Since then the introduction of Brahma and Crève-Cœur has greatly improved the breed of the fowls.

The number of eggs annually laid by a fowl is estimated at fifty-two, which would weigh about 6 lbs., and as a fowl seldom weighs more than 3 lbs., a hen lays annually eggs double her own weight. Seventeen eggs will weigh on the average a kilogramme, or 2½ lbs. Honfleur eggs are regarded as the best in France, and generally fetch from 1s. to 1s. 6d. the hundred more than Cherbourg eggs. The Cherbourg cases contain about 1125 eggs each, and the half-cases from Honfleur 600. They arrive chiefly at Southampton, but imports are also made at Bristol, Weymouth, Poole, Shoreham, Newhaven, and Littlehampton. The Brighton and South-Western lines bring up 12,000 tons of French eggs a-year, or more than 4,000,000 a-week all the year round. The quantity shipped from Calais in 1874 was 503,100 kilogrammes in weight, or about 9,500,000 eggs. Mr. Hotham the British Consul at Calais, points out that the nature of the soil has much to do with the quantities of eggs laid. "In this neighbourhood," he remarks, "as well as near Boulogne, there exists a marked quantity of silica in the soil, highly favourable for egg-laying purposes; remove the fowls from this peculiar soil, and this fecundity ceases, and that this is the case about here as well as in the neighbourhood of Boulogne is well known." At Amiens, again, this same quality of soil is found, and the poultry from that district are remarkable for their laying qualities; indeed, they are the "most celebrated layers in France."—(*Grocer.*)

PIGEONS AT BIRMINGHAM.

I SEE in your report of the Pigeons at Bristol that "WILSON'S RACON" alludes to the temperature of the Pigeon-gallery at Birmingham. I have visited that place at all hours, and can entirely corroborate what he states. The object, however, of my troubling you with these lines is to suggest that fanciers should join in a friendly remonstrance to the authorities before refusing to enter. I have found those in charge of the birds at Birmingham particularly obliging. At 4 P.M. on the Wednesday of the last Show I found the atmosphere in one part of the Pigeon-gallery quite unbearable from the gas below. I had no birds at that end, but for kindness' sake found the person in charge, who at once altered the gas and ventilators, and things were a little improved. Still nothing can make that gallery a proper place for Pigeons. Remonstrance has gained us much in the poultry department. Three years ago the birds spent a week on boards saturated with water from those wretched drinking-dishes, now they have sand (certainly little enough), supplied, proper drinking vessels hung up, and green food given daily. I shall be glad to join any fanciers in pleading for better treatment of the Pigeons.—O. E. CHASSWELL.

THE LARGEST POULTRY-YARDS

In New York State are at Greene, Chenango County, kept by Mr. A. B. Robeson. He has 6000 Ducks, 4000 Turkeys, and 1200 hens. They consume daily sixty bushels of corn, two barrels of meal, two barrels of potatoes, and a quantity of charcoal. The meal, potatoes, and charcoal are boiled together and form a pudding, which is fed warm. He has commenced to kill them off, and employs fifteen hands to pick, two to kill, and one to carry away and pack on racks until frozen, then they are ready to pack for shipping. He also employs two men to cook the feed and feed them. He has twelve buildings for his fowls, from 100 to 200 feet long, 14 feet wide, and 7 feet under the eaves, with a door in each end of them.

Mr. Robeson bought most of his Ducks in the West, and had them shipped in crates—three dozen in a crate. He also has an egg-house, 35 by 50 feet, and four storeys high. The outside is 18 inches thick, and built of cut stone, laid in mortar, boarded-up on the inside and filled-in between the outside and inside wall with sawdust, it taking 3000 bushels. Mr. Robeson claims that he can keep eggs any length of time in this building. He also keeps the poultry that he is now dressing until May or June, which sells for 18 to 25 cents per lb., and it cannot be told from fresh-dressed poultry. He gets 10 cents per lb. for Turkeys' feathers, 12 for hens, and 65 for Ducks. He says that there is money in poultry, and he thinks he can make out of his 6000 Ducks enough to pay for his egg house, which cost \$7,000. He intends to keep a great many more next season, and has agents out all over the country buying up poultry and eggs.—(*American Fanciers' Journal.*)

LABURNUM SEEDS POISONOUS.—Are the seeds of the laburnum poisonous? I have a tree growing in my fowl yard, the seeds from which have been falling for the last few weeks, during

which time several fine fowls in good condition have died suddenly.—W. BENNETT.

[The seeds of the laburnum are poisonous. There are many instances recorded of children being killed by eating them.—Eds.]

DO BEES TERRIFY CATTLE?

I WAS reminded by the remarks of "C." on hive bees as predatory insects, in the *Journal of Horticulture* the other week, of a complaint sometimes made against these bees by cattle graziers. During warm and sultry days in July and August, in the time of the white clover, the hive bee is at times accused of causing cattle to run about and be unsettled. All acquainted with rural affairs have noticed, in warm summer weather, cattle careering along or around their pastures, panting, foaming, and sweating, with their tails turned into the air or sticking out in a line with their body, seeking some stream to plunge into or find the shelter of trees or houses, all apparently trying to escape from some, to us, unseen foe. Now the humming or buzzing of bees are often blamed for this.

I should like to know the opinion of experienced bee-keepers on this subject. I think bees have little, if anything, to do with the matter, and this is one reason I have:—Some years ago, around the garden where my bees are kept, was a field of pasture with the ordinary quantity of white clover in full bloom. The bees, to get to the field, had to fly over an elder hedge that grew round the garden. Did the many thousands of bees crossing the hedge frighten away the cattle? Nay, verily; but so much did they like to chew and tear among the branches that an outer fence had actually to be erected to prevent them from destroying it altogether. The hives were close at the inside of the hedge, and I considered that I had some good ground for thinking that the humming of bees at work did not disturb cattle.—JAMES SHERRER, *Aberdeenshire.*

UNITING A LIGURIAN QUEEN TO COMMON BEES.

We cannot answer "Nemo" better than by extracting the following from our "Bee-keeping" manual:—

"As soon as you have become possessed of a Ligurian queen and her attendants, steps should be taken for removing the common queen from the stock or swarm to which the strangers are to be united.

"Where bar hives are in use the operation is sufficiently easy, but should not be attempted without the protection afforded by a bee-dress and thick pair of woollen gloves. The services of an assistant similarly accoutred will be found very useful, but are not absolutely indispensable.

"The middle of a fine day is the best time for the operation, which should be commenced by removing the stock a little either to the right or left of its usual position, which must be occupied by an empty hive, from which the top-board and comb-bars have been removed. The top-board of the full hive must then be shifted on one side sufficiently to expose a single bar, which may be carefully withdrawn after the attachments of the comb have been severed from the back and front of the hive by a bent knife. Both sides of the comb must be rigidly scrutinised, and any cluster of bees gently dispersed with a feather, until it becomes evident that the queen is not present, when it may be placed in the empty hive. The same process must be repeated with each successive comb until the queen is discovered and secured, when the bees may be either allowed to remain in the hive to which they have been transferred, or replaced in their original domicile. Sometimes the queen is not to be found on any of the combs, but may be detected among the stragglers remaining in the hive. In practised hands her discovery may be reckoned on with tolerable certainty during the first removal; but if she succeed in escaping detection the process must be repeated until she is secured.

"With common hives or boxes driving is the best method to adopt; and the bees, having been expelled from their habitation, may be knocked out on a cloth and searched over until the queen is discovered.

"Should the bee-keeper be unable to perform the operation of driving, fumigation may be resorted to, and the queen secured whilst the bees are in a state of insensibility.

"Should the queen have been removed and the bees restored to their original hive and position in the apiary, measures must now be taken to introduce the Italian sovereign to her future subjects. The first step will be carefully to remove the lid of the small box, replacing it with a slip of perforated zinc without permitting the bees to escape. The whole must then be inverted over an opening in the top of the hive containing the queenless stock, where it should remain undisturbed till the next day, when the perforated zinc divider may be withdrawn, and the union will be complete. The small box itself need not be re-

EPIPHYLLUMS—TABLE DECORATIONS.—No. 1.

LATE in autumn, also throughout the winter, these are amongst the gayest and most useful of decorative flowering plants. Their graceful pendant habit, combined with flowers mostly shades of red, with purple or violet shading and white throats, produced from the points of the arching shoots, and being very floriferous, render them particularly ornamental, especially when viewed by artificial light.

Need we be surprised that in the usual brilliancy of rooms by lights, mirrors, &c., contrasting objects are introduced to give tone—often intentionally higher tone, but in reality subduing, rendering more agreeable the objects that without such rest for the eye would, after a first impression, be oppressive? Plants upon a dining-table, or vases, &c., of flowers with the indispensable sprays of green foliage are to the guests what an oasis is to the traverser of a desert, or the relief found in the evergreens when the ground is covered with snow. In that sense, and that only, can I see the fitness of plants or flowers for dinner-table decoration; they are employed to ornament, and at the same time subdue, and render more agreeable the brilliancy of their settings.

Light and shiny substances have the greatest foil in black, but the contrast is not pleasing. Dark objects become in the distance apparently blue, as that of the sea and sky, which makes a ship with sails unfurled so prominent an object on the water. But if we multiply the ship into a fleet of ships its individuality and distinctness is absorbed into the mass of white. It is the same with plants and flowers. Pretty, indeed, all flowers are, but if embedded in dining-tables to represent a parterre their individual beauties are frittered away. Plants employed in table decorations to be effective must have their individual forms preserved, while their arrangement must be in harmony with their surroundings.

If the articles upon the table be massive, to arrange the plants or flowers massively, or so as to appear so, is still to render the whole more heavy; whilst to have light plants or flowers lightly arranged is to make more prominently massive their heavier surroundings, and yet this is the most pleasing combination; for when the objects are few and massive the plants which are to relieve them must be few in number, graceful, and elegant, for in this as in everything else beauty is not to be sought by adding to what is possessed in full by an object, but what is wanted is a "finish," which in most instances is found in diametrically opposed forms; for what so beautiful as the tree or shrub of graceful habit viewed across a breadth of closely-mown verdant lawn, or the spray of a Willow whipping the waters of a lake?

Flat surfaces are not tastefully decorated by low plants, and stiff formal objects have not fitting contrasts in the stiff and erect habit of trees. To plant a valley with tall trees is to convert it, so far as trees can do so, into a plain, making a level of a hollow, destroying those undulations

of surface which are so pleasing in the landscape; whilst to plant a hill with Pines is not only to make an object a feature in the landscape, but to make the hill higher and the hollows appear deeper.

It is the same even with the dinner-table as with other decorations, admitting of many combinations, and into which will creep incongruous innovations, not the least being that of converting the table into mimic flower beds cut in the cloth, with lead forms let into the table, the forms raised of clay and filled with flowers, than which nothing can be in worse taste. Flat and formal arrangements of flowers such as that can only be compared to the offering of prizes at rural flower shows for designs for villa gardens, which though exhibiting much ingenuity are at best toys, and further no purpose but that of mimicking the real and frustrating any advance in useful horticulture.

It has already been stated that the greatest contrast to white is black; bright shining substances, however, are intensified, not in contrast with black, but are most brilliant upon a white ground—the white heightening the tone of that to which it is contiguous, but the black from the effect of the white light is more or less destroyed by the reflection by the black of the light of the white. All the primary colours—red, yellow, and blue of painters (which are not those of the prismatic spectrum)—gain by their juxtaposition with white, and when white surfaces are viewed simultaneously with coloured objects contiguous to them they are sensibly modified.

White heightens light tones of any colour, and possesses the advantage of separating those whose colours are mutually injurious: hence the green of plants is the greatest relief to the eye from the whiteness and brightness of a dining-table; but it must not be supposed from that that they are the most effective. Beautiful as are the finely-divided fronds and gracefulness of Ferns, or the more stately yet elegant (and glaucous in some instances) forms of Palms, they are not so effective as if the plants employed combine red with green, as instance the coral berries of *Nertera depressa* on moss-like foliage, the berries of the Holly when the ground is snow-clad, and the scarlet bracts of *Poinsettia pulcherrima*; the same applies to drooping or to erect forms, the red being beneath or associated with the green, as *Russelia juncea*, *Thyracanthus rutilans*, or *Epiphyllums*; also in combination with green, as in some *Dracenas*, the bright pink of the young fronds of some Ferns, as *Lomarias*, being very telling when the plants have deep green fronds as well. Green and yellow, as that of *Oroton Johannis*, are not so effective as those of *Oroton undulatum*, which in the mature state has crimson markings, and the same remarks apply to *Dracenas*. Those having beauty in the highest degree are those combining red with green, though in some, as *D. amabilis*, the green, white, and pink are presented in the foliage, which is very pleasing.

Plants with white stripes in the centre or the variegation disposed on the margin of the leaves accord well, but silvery-leaved plants, as a rule, are not effective; yet plants with a

silvery lustre on a dark ground as that of *Aralia Veitchii*, and a contrasting hue as this has on the under surface, being dark red, the effect is splendid; this is probably the finest representative of a table plant we possess. White flowers appearing above or amid green or marbled foliage with red under surface, as *Cyclamens*, are appropriate, yet the effect is considered heightened by the addition of red; for white we have sufficient in the cloth, and shining objects enough in its accompaniments; we require first green, then red, and separating by white interspersed with green; other shades of colour, as yellow, contrasting with maroon or other deep shades of colour up to black. Pink and rose colours are made to appear brighter and deeper by contrast with deeper-tinted colours, and with green, when viewed under artificial light, are good in contrast with white or yellow under lamplight. Purples under night lights lose all the blue and become lighter or deeper shades of red as they are light or deep by day in purple colouring. Orange is a fiery scarlet, very bright; and flowers tinged with lilac, as *Primula sinensis* var., are intensified in colour under artificial light. Plants with marbled foliage and metallic-lustered, as *Cissus discolor*, are very beautiful, and most plants with veined foliage are effective. As a rule bright colours are intensified by artificial light, and yet without green they have a heavy appearance. In the matter of form almost all plants of graceful aspect with finely-divided parts or long and narrow foliage are available for the table.

Orchids always have so much dissimilarity with other subjects as to accord well; but their flowers only have this advantage, as the habits of the plants are in a majority of cases highly objectionable from a decorative point of view. Exception must, however, be made of some *Cypripediums*, *C. venustum* being very useful, and the *C. barbatum* vars. and the singular *C. caudatum*, whilst the very common *C. insignis* is a very effective plant. The dwarfest of the Pitcher-plants tell well, especially the New Holland one, *Cephalotus follicularis*; whilst no plants under light are more beautiful than the Sundews, a well-filled pot of *Drosera rotundifolia* being very appropriate. Berried plants, as *Solanum capsicastrum* with its orange-yellow berries, or even *Capsicum* as *Prince of Wales* with its bright lemon-coloured pods, and the deeper and more telling *Yellow Gem*; and there is a kind of *Capsicum* with bright red Cherry-like pods which is very effective. But as I have carried this dissertation much further than was intended I shall close with a few observations as to height.

It is, I think, a generally accepted principle that the plants should be of such a height, or so disposed, as not to interrupt the view of guests from one side to another. It is clear the plants must be low if when seated conversation is to be carried on across the table, but *Dracenas*, *Aralias*, *Palms*, and other plants have the foliage so disposed as to admit of a view through; and these I consider, from their greater distinctness, lightness, and clearness of feature, are the truest representatives of that contrasting elegance which is required in dinner-table plants.

Some plants are best seen as tall or standard plants. Of this class are most berried plants and the plants at the head of this article, of which culturally I must refrain comment for another communication.—G. ASBRY.

FRUIT PROSPECTS—PRUNING.

I AM afraid that the past summer will long leave its marks on our fruit trees. When I saw the Plum and Pear leaves taking on their autumnal colours, and falling rapidly when touched by the breeze, I was in hopes that in spite of the absence of light and heat the trees had somehow managed to do their work perfectly; but, on applying the pruning-knife a different tale was told, the wood is weak and green beyond all precedent. There are plenty of fruit buds, but oh! so puny that it seems impossible for many of them to be perfect, and I fear the chances of another fruitful year like the one just past are rather remote.

I do not want to raise needless alarm, but it is as well to take a survey of the situation and see as near as we are able what are our chances of success, in order to be able better to direct our actions. For my own part I not only expect fruit to be scanty, but that the trees will also be very seriously injured. Unripe wood, where it is left and survives the winter, will be a prey to canker and all diseases and insects which fruit trees are subject to. Where wood is unripe, too, of course the roots are in the same condition, and will in conse-

quence die-back more than usual, and be later in starting in spring, although the upper portion of the plant will not wait for them.

What, then, is to be done? I will endeavour to say what I have done, and leave others to judge for themselves whether it is worth while to take a leaf out of my book. I have given up pinning over the prospect of scanty crops this year, and am looking farther a-head. I will do the best I can to keep my trees healthy, and to this end I have gone from my usual plan and have pruned all trees not grown against walls very hard indeed, relying for fruit principally on spurs situated on the old wood.

Trees which have grown unshapely or are weakly, I have taken the opportunity to cut-back with a saw so as to bring them into a goodly form. Had there been an immediate prospect of fruit on them I should have hesitated to take such extreme measures, and the trees in a few years would have become unsightly or useless; now I hope to be rewarded with good-formed trees next year, and if the seasons permit with fruit of good quality in the year following.

Trees on walls, with the exception of Peaches, are much better matured. The last-named I thought it advisable to partially protect from the severe frosts we had before the leaves had all fallen. The fruit buds are better developed on the cordon trees than on those trained in the usual way. Bullfinches, though numerous, have not yet attacked the fruit buds. I am afraid this is a bad omen, they do not think them good enough.

I envied a gardener writing from the north in a contemporary last month, where he said though the frost was severe the wood was thoroughly ripe and would not be injured. Is such really the fact? If so, I shall be inclined to go northward to see some fruit when the time comes. I am afraid many people, however, take only a very superficial view of the case. I would advise another look; and although the end of January is later than pruning ought to be done, it would be better to prune even in March than leave unripe wood, and where the wood is in the same pitiable condition as it is in this neighbourhood I say, Prune hard.—WILLIAM TAYLOR.

RANUNCULUSES IN POTS.

SELDOM are these beautiful spring flowers cultivated in pots for the decoration of the conservatory, while *Orocuses* and *Tulips* are so grown in hundreds of thousands. That the latter are gay is not disputed, we will even admit them to be gorgeous; but yet they are favoured by fashion, for for true beauty neither one nor the other can rival well-grown pots of *Ranunculuses*.

Ranunculuses are cheap, are of the easiest culture, and when in bloom are not only most ornamental, but their flowers are admirably adapted for cutting for vase-decoration. *Ranunculuses* will, however, not force after the manner of the other bulbous flowers alluded to, and that is, perhaps, the reason why they are so seldom cultivated in pots. Yet if they will not force, according to the common acceptance of the term, their flowering may be accelerated some weeks, or, at any rate, distinctly before those in the open ground unfold their beauty.

Both sections of *Ranunculuses* may be grown in pots, but the *Turbans* are preferable to the *Persians* by the greater massiveness of the former and their earlier-flowering nature. Pots of the brilliant scarlet and pure white varieties when well managed—the foliage of the plants healthy and the flowers robust—are amongst the most effective of low-growing decorative plants in the early spring months.

In order to have them blooming at the earliest stage and in the best condition, the roots should be potted in October and be plunged in ashes in cold frames, the surface of the pots being also slightly covered with ashes or cocoa-nut fibre refuse. But even if potted now the plants will make an excellent display, and are sure to be admired if well cultivated.

For pot culture the finest roots should be selected, and five should be placed in a 6-inch pot. The soil cannot be too heavy and rich, except the inch at the top of the pots in which the roots are in immediate contact, and this should be light and sandy. The pots should be plunged in ashes, and should be kept plunged until the flowers show colour, of course allowing the plants sufficient room to develop themselves. They only need a cold frame, and protection from frost with mats or other covering. When in growth the plants cannot have too much light, and as their growth increases so must the supply of water. Drought at the roots is fatal to healthy

foliage and fine flowers; hence it is advisable to keep the pots plunged.

By a judicious system of airing, the frame treatment will bring the plants into flower three weeks earlier than those planted in the garden, and they will be equally fine. A most important point is to keep the glass clean, for with light the plants will not be injuriously drawn even if only a small quantity of air is admitted, and the warmer temperature will expedite the blooming season.

I have been in the habit of growing bulbs largely, and, next to the Hyacinths, the Ranunculuses have been the most prized. If a failure occurred it arose from exposing the pots to a dry atmosphere, and in attempting to force the plants in a higher temperature than they would endure. A cool frame, judicious attention, and patience have always brought me a reward of healthy plants and handsome flowers. As they have rewarded me so will they others who treat the plants similarly. Try them.—R. C. B.

HÆMATOXYLON CAMPECHIANUM.

THIS evergreen stove plant, which attains to a moderately-sized tree in South America, furnishes the logwood of com-

Fig. 12.—*Hæmatoxylon campechianum*.

merce, and from the colour of which its name is derived—*haima*, blood, and *xylon*, wood. It belongs to the order of Leguminous plants, and has agreeable foliage and slender racemes of yellow flowers. It is of easy cultivation and may be readily increased from seeds, which, however, germinate more freely if steeped in warm water for some hours before sowing. Cuttings of partially-ripened young shoots also strike freely in sand under a bellglass. A compost of loam, peat, and sand is suited to the requirements of this plant with a temperature in summer of 70° to 85°, and in winter 50° to 55°.

It is a native of Campeachy, the shores of Honduras Bay, and other parts of tropical America; but it has been introduced into Jamaica, where it has become naturalised. The flowers are fragrant, and give out an agreeable odour said to resemble that of the Jonquil. The wood is hard, compact, and heavy, with a specific gravity higher than that of water; has

a fine grain, and is susceptible of a fine polish. It is chiefly employed by the calico printer to give cotton a black or a brown colour; if it be dyed with an alum mordant in a decoction of logwood it becomes black. It was first cultivated in Jamaica in 1715, from seeds brought from the Bay of Campeachy, and was introduced into English gardens in 1724. Its colouring properties depend on a peculiar principle called *hematoxylin* or *hematin*.

MISTLETOE CULTURE.

MR. KENTISH in his entertaining paper has stated that the Mistletoe cannot keep the tree alive on which it is growing, neither can it support itself if its foster parent is denuded of its own growth. This may be true, yet the Mistletoe will flourish when the tree to which it is attached has but very few live twigs. Some of the finest "Mistletoe boughs" that I have seen were those on which the parasite had so far taken possession of a tree that the growth of that tree was almost entirely subdued: still there were some live twigs.

But what I wish to particularly mention now is a mode of growing the Mistletoe which I once saw in the nursery of Mr. Charles Van Geert at Antwerp. These were miniature Mistletoe trees grown precisely after the manner of standard Roses. The stems, if I recollect rightly, were Thorn, 3 to 4 feet high, and the heads of Mistletoe were round, dense, and about a foot in diameter, some being covered with fruit. But in these heads a few twigs of Thorn were encouraged to grow, but they were so few as scarcely to be noticeable. These miniature Mistletoe trees had a most novel appearance, and I was not surprised to hear that they had sold rapidly. Only a very few were left at the time of my visit.

It would be instructive to know if Mistletoe can with any degree of certainty be cultivated in that manner, and whether it is established by grafting or seeds. It is an experiment that might well be made in the Mistletoe-growing districts, and plants similar to those which Mr. Van Geert had produced at Antwerp could not fail to create a sensation in Covent Garden Market at Christmas time.—J. B.

OLD APPLE TREES.

THE able way your correspondent "RADICAL CONSERVATIVE" has treated the subject of old trees at page 82 leaves little to be said, and what I may add shall be confined to old Apple trees. I confess, like "RADICAL CONSERVATIVE," to have some misgiving on the subject of pruning old Apple trees, but I differ with him entirely on the subject of heading-down and regrafting them; for although the scions may take very well, and a strong growth follow, it often happens that the trees die in less than half a dozen years after the operation, and long before a similar tree would have succumbed that had not been so treated. So repeatedly is this the case that the experienced orchard manager knows at a glance whether it is worth while subjecting a tree to the process or not.

As an example of this I may mention a case that has only received its final termination the day I write this. Three years ago I received a number of grafts of new kinds of Apples which I was anxious to propagate, but not having young stocks, an old tree was cut down. The tree was healthy, and on an average might yield, perhaps, a dozen or more bushels of fruit annually. Well, the branches of this tree were cut off mostly at places where they were as thick as the handle of an ordinary working tool, and were crown-grafted. The scions took very well, and for two years looked promising, but last year I found one-third of the tree died in early summer and a similar portion later on, leaving only a distorted, one-sided, ugly object that evidently was only likely to drag out a wretched existence, so the spade and mattock made short work of it to-day. I may add that I had previously secured scions of most of the kinds the year after the tree was grafted, as its death was not unlooked for; and I only mention it here to prove the inutility of regrafting old trees, for the fellows to this one that were operated upon are still healthy and bearing, one or more of them having had twenty bushels of fruit on it the past season, and likely to do service for many years yet. So much for regrafting old trees.

And now to the matter of pruning old trees. The operation performed above was only an extreme case of pruning, the tree being only cut down, or rather its branches cut off, leaving some forty or fifty heads or points, but showing in the result

the same progress of mischief that follows less severe pruning. An old tree cannot endure severe amputation. Our hospitals, like our orchards, prove that with the aged surgical operations are likely to prove fatal; the old Apple tree might continue to do good service if left alone for several years, but subject it to the surgical operation of the pruner and it gradually succumbs. It is for this reason that old trees during the latter part of their fruit-bearing lifetime are in general left alone in the orchards in Kent, and the knowledge that it is best to do so has not been arrived at without plenty of failures in pruning and attempting to improve the appearance of the trees. I may say, as the result of much practice and observation, that in general neither the knife nor saw ought to be used to an Apple tree during the last ten years of its life, assuming it is expected to arrive at the age of forty or fifty years. Of course there are plenty of trees in a fair bearing state older than this, and many are old and worn out before that time, so that some discretion is required to judge when to cease the pruning, and the practised eye can easily tell this by the appearance of the trees.

Much has been said of the thickness of the centre of an unpruned tree. I have an opportunity of seeing hundreds of unpruned Apple trees, and their centres invariably consist of naked limbs; it is nearer the outside where the thicket really is. Supposing an aged tree is left alone a number of years, the densest part of that tree will be found within 3 feet of the extremities of the branches; and what fruit there is, much inside the outer ends of the branches is never of any account. Generally there is plenty of room for a heavy crop on those branches that project outwards, and the bulk of the fruit will be found within 2 feet of their extremities. "Opening out the centre of a tree" seems to me a process only required in very young trees, Nature doing it for us in the old. Those who want to hasten the decay and death of an Apple tree, however young, cannot do better than persistently follow up the practice of finger-and-thumb pinching in summer; their tree will be on the rubbish heap before their neighbour's which has been let alone has fairly arrived at its best, and the produce of the latter will probably have been many fold that of the former. My final advice on the subject of old Apple trees is either to let them alone or destroy them entirely, for I have found no middle course satisfactory.—J. ROSSON.

REPORT ON CELERIES

GROWN FOR TRIAL BY THE FRUIT AND VEGETABLE COMMITTEE OF THE ROYAL HORTICULTURAL SOCIETY AT CHISWICK 1874-5.

THE seed for this trial was presented by Messrs. Carter and Co.; Messrs. Barr & Sugden; Messrs. Minier, Nash, & Nash; Messrs. Harrison & Sons; Messrs. Osborn & Sons; Messrs. Stuart & Main; Messrs. Veitch & Sons; Messrs. Vilmorin et Cie.; Samuel Simpson, Esq.; Mr. B. Dean, and Mr. A. Parsons.

There were forty-seven reputed varieties received, of which twenty-three were red and twenty-four white. These the Committee by the detection of numerous synonyms reduced to twenty—viz., seven red varieties and thirteen white, which have been decided to be distinct.

The seed was sown early in March in heat, and the plants pricked-off and planted-out early in June in single trenches, and treated after the ordinary manner. The plants were frequently examined by the Committee whilst growing, and again when fully grown, and a portion of each sort was left to test their capabilities of standing the winter.

The season of 1874 was a particularly favourable one for the growth of Celeries, so that the trial was a satisfactory one.

1. RED VARIETIES.

1. MANCHESTER RED [*synonyms*, Laing's Mammoth, Radford's Pink, Sulham Prize Pink, Hooley's Conqueror Prize, True Manchester, and Giant Red].—Plant of strong and vigorous growth, attaining an average height of 3 feet 4 inches. Leaflets broad green. Heads compact, average girth 12 inches. The outer leafstalks are moderately broad, slightly shaded with red. Heart very solid; the stalks, broad, thick, and fleshy, blanching for about 12 inches. A very excellent sort, stands the winter well. This is the largest variety.

2. IVEY'S NONSUCH [*syns.*, Violet de Tours, Osborn's Select Red; London Market; Red].—Plant of strong and vigorous growth and habit, average height 3 feet. The leaflets are broad, deep green, the pinnae more widely situate than in

other varieties. Heads compact, average girth 12 inches. The outer leafstalks flat, of a deep rosy-red colour. Hearts very solid, blanching for about 18 inches. Stalks very solid, broad, thick, and crisp, of a fine nutty flavour. A very excellent sort, and one of the best to stand the winter.

3. KIMBURY'S RED [*syns.*, Improved Solid Red; Stuart and Main's Solid Red].—Plant of regular but somewhat spreading habit of growth. Height 2 feet 6 inches. Leaflets broad, deep green. Heads compact; average girth 11 inches; the outer leaflets narrow, rounded, and slender, of a deep rosy red colour. Hearts very solid, blanching for about 12 inches; the stalks broad, thick, and crisp, of a fine nutty flavour.

4. CARTER'S INCOMPARABLE CRIMSON [*syns.*, Carter's Incomparable Dwarf Crimson; Hood's Dwarf Red].—Plant of close compact growth. Height 2 feet 6 inches. Leaflets rather broad, pale green. Heads very compact; average girth 11 inches. Outer leaflets narrow, deep rosy pink. Hearts very solid, blanching for about 11 inches; the stalks thick and fleshy, and of fine quality. This is the dwarfiest red Celery, and a good hardy variety to stand the winter.

5. WEBSTER'S No. 1. [*syn.*, Webster's No. 4].—Plant of somewhat slender growth. Height 2 feet 10 inches. Leaflets broad with short petioles, giving it a bushy compact appearance. Heads compact, average girth 10½ inches; outer leafstalks slender and narrow. Heart solid, blanching for about 12 inches. The stalks solid, thick, very crisp, and of good quality.

6. LEICESTER RED [*syns.*, Major Clarke's Solid Red, Turnmoss Red, Ramsey's Solid Red].—Plant of erect compact growth, presenting a very uniform appearance when growing. Height 3 feet. Leaflets rather small, deeply serrated, of a shining green colour, with a sort of silvery shade. Heads very round and compact; average girth 12 inches. The outer leafstalks are rather narrow or rounded, of a clear rosy pink colour. Hearts very solid, blanching well for about 12 inches; the inner stalks broad and thick, very crisp, and of a fine nutty flavour. One peculiarity of this Celery is, that of the core rising about 2 inches in the heart, as if it were to run to seed. This core portion is by many considered the best part. This variety from its close compact growth blanches easily, and is the best Celery for autumn or early-winter use, but it does not stand the winter well.

7. WRIGHT'S IMPROVED GROVE RED.—Plant of the same appearance as Leicester Red, but somewhat dwarfer. The heads are also larger, being 18 inches in circumference. Hearts large, very solid, and good. This is a very excellent sort.

2. WHITE VARIETIES.

8. GROVE WHITE.—Plant of strong and robust growth. Height 2 feet 9 inches. This is an exact counterpart of the Grove Red, but white and possessed of the same excellent qualities. Does not stand the winter so well as other sorts.

9. INCOMPARABLE DWARF WHITE [*syns.*, Plain Blanc Court Hatif, Sandringham, Dean's Compact White].—Plant of very dwarf and compact growth. Height about 24 inches. Leaflets small, pale green. Heads very compact, average girth about 10 inches. Outer leafstalks broad and deeply ribbed. Hearts solid, blanching about 10 inches, and of a pure white. The stalks broad, thick, fleshy, crisp, and of fine quality. This is one of the best sorts, its close dwarf growth renders it easy to blanch with remarkably little earthing-up. It is good for early use, and also stands the winter well.

10. PLAIN BLANC.—Plant of dwarf compact habit. Height 24 inches. This is much of the same character as the preceding, but smaller and inferior. It is useful for an early supply.

11. A COURER.—Plant small, height about 24 inches. Leaflets small. Heads small, outer leafstalks very narrow. This is not of much use only for very early work, the small heart blanching very quickly. It soon runs to seed.

12. TUNC GRAND.—Plant of robust growth. Height 2 feet 6 inches. Leaflets large, broad deep green; outer leafstalks broad, much ribbed. Heart small. It may be useful for an early supply, but soon runs to seed.

13. SETMOUR'S WHITE [*syns.*, Goodwin's White; Northumberland Champion White].—Plant of somewhat spreading habit of growth. Height 3 feet. Heads large, 12 inches in girth. Outer leafstalks broad, very deeply ribbed. Hearts solid, blanching to nearly 14 inches. The stalks broad, thick, and fleshy. This is the largest-growing white Celery, and apt to become pithy if very strongly grown.

14. PRINCESTON WHITE [*syn.*, Veitch's Silver White].—Plant of somewhat slender growth. Height 3 feet. Leaflets

small, deep green, sharply serrated. Heads large, girth 11 inches. Outer leafstalks narrow. Hearts somewhat loose, blanching to about 12 inches. The stalks rather soft but of fine flavour. Rather tender.

15. **DIXON'S MAMMOTH WHITE.**—Plant of close compact robust growth. Height 2 feet 8 inches. Leaflets broad. Heads large, girth 14 inches; outer leafstalks very broad, about 2 inches. Hearts very large, blanching about 11 inches, somewhat soft, but excellent. It stands the winter well.

16. **GREAT EASTERN.**—Plant of loose spreading habit, so much so that it is difficult to keep the heads together, and much addicted to throwing-up side shoots. Height 2 feet 9 inches. Leaflets small pointed, very pale green. Heads small, girth 10 inches. Hearts loose and small. A very worthless sort, and decays early.

17. **HAYWOOD'S WHITE QUEEN** [*syn.*, Stuart & Mein's Giant White; Goodall's Flat-stalked; Webster's White].—Plant of robust growth. Leaves spreading. Height 2 feet 9 inches. Heads large, 13 inches in girth; outer leafstalks very broad (about 2 inches), much ribbed, and coarse. Hearts solid, blanching to about 14 inches. The stalks very large, broad, thick, and fleshy; but without much flavour. An excellent sort to stand the winter.

18. **VEITCH'S SOLID WHITE** [*syn.*, Danesbury].—Plant of close compact growth. Height 2 feet 6 inches. Leaflets broad, very deeply toothed or serrated, giving it quite a distinct appearance. Heads compact, girth 11 inches; outer leafstalks rather broad, deeply ribbed, pale green. Hearts very firm and solid, blanching for about 12 inches. The stalks broad, thick, crisp, and tender. A very excellent variety, and stands the winter well.

19. **BOSTON MARKET.**—Plant dwarf, from 18 to 20 inches high. Leaflets small pointed and sharply serrated. This variety is not used to produce a single head as the ordinary Celeries, but having the peculiarity of forming a number of side shoots or small heads which are blanched. It is suited for early work, and it begins to run to seed almost as soon as planted out.

20. **FRISK, Curled or Garnishing.**—Plant of loose growth. Height about 2 feet. Leaves very pale green, and deeply cut or curled almost like Parsley. It is very ornamental. The leaves may be used for garnishing, but it is of no other use. It is very tender, and runs early to seed.

21. **TURNIP-ROOTED** [*syn.*, Celeri navet; Rave; Raved' Erfurt; Soup Celery].—This is quite a distinct vegetable, the plant forming a large bulb at the base of leafstalks like a Turnip. This bulb is used in soups much in the same way as Turnips, and not the leafstalks as in other Celeries, and requires no blanching. It is not much cultivated in this country.—A. F. BARNON.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 19TH.

FRUIT COMMITTEE.—Henry Webb, Esq., in the chair. Mr. Walker of Thame sent bulbs of his Model Long-keeping Onion, which is identical with White Spanish, except that the skin is tinged with brown. A dish of Witloof or Hearting Chicomery was exhibited from the gardens of the Royal Horticultural Society from seed supplied by Messrs. James Carter & Co. This excellent salad vegetable had been blanched in the way of Seakale, and was awarded a first-class certificate. Mr. William Taylor, the Gardens, Longleat, sent a dish of Orangefield Tomato which was much commended. Messrs. Stuart & Mein sent a collection of Chilian Beet of various colours, to which a letter of thanks was awarded. The same gentlemen also sent specimens of a prolific Scotch Kale which formed secondary curled blades on the leaves, to which a letter of thanks was awarded.

Mr. Chambers, Westlake Nursery, Springrove, sent a box of Blenheim Pippin Apples, to which a letter of thanks was awarded. Mr. Cox exhibited a dish of Redleaf Russet, which received a first-class certificate last year, and these quite confirmed the good opinion formed of it by the Committee. A dish of Beurré de Jonghe Pear was received from the garden at Chiswick, and was found to be of exquisite flavour. Josephine de Malines was also very well flavoured. Beurré Sterckmans and Belle de Noël were not so well flavoured, some of them not being quite ripe. Glout Morceau and St. Germain were of good but not high flavour.

Mr. William Paul having offered a prize for the best bunch of Waltham Cross Grape exhibited before the Society in January, 1876, two competitors exhibited, and the prize of £10 was awarded to Mr. James Douglas, Loxford Hall.

FLORAL COMMITTEE.—B. B. Peckans, Esq., in the chair. At this the opening meeting of the year there was a considerable attendance of horticulturists. The day being mild also per-

mitted the removal of tender plants from their homes, and Messrs. Veitch consequently made a most attractive exhibition. Only one first-class certificate was awarded on this occasion, this honour going to an Australian Dendrobe exhibited by Mr. Denning, gardener to Lord Londesborough—*Dendrobium teretifolium*. This remarkable plant has straw-coloured flowers individually small, but striking by their great profusion. The plant is growing on wood, the foliage having a curious resemblance to gigantic roots which hang perpendicularly from the slender suffrutescent stems. It is a very distinct species, and has been appropriately alluded to as the Cobweb Orchid.

Messrs. Veitch & Sons' splendid display consisted of about fifty Orchids, a few Palms, hybrid Amaryllises, and other ornamental plants. Amongst the Orchids were *Cypripediums* *Crossianum*, *tessellatum*, *Argus*, and *Schlummi album*; *Odontoglossums* were represented by *O. Roezlii*, *Roezlii album*, *Rossii majus*, *Alexandra*, *Hallii*, *Pescatorei*, *Bicolorense splendens*, *O. Phalaenopsis* and *Andersonii*. Amongst *Cattleyas* were *Skinnerii* in variety, and *trianae*. Noticeable also were *Oncidium cheilophorum*, *Masdevallia tovarensis* very fine, *Angraecum sesquipedale* with six blooms, and *Sophranthes grandiflora* extremely bright. Besides the Orchids, *Anacochilus Dawsonii* had eight spikes of flowers, and *Tillandsia Lindenii* was remarkably robust, one stout spike having flowers, and four other spikes were clear of the axils. More vigorous still was *T. Zahnii*. Exceedingly brilliant was *Aphelandra aurantiaca* *Roezlii*, the plants being dwarf and very fine; it is difficult to imagine a more fiery colour than is possessed by the spikes of this fine plant. The *Amaryllises* were in colours of cream, crimson, and scarlet, striped, mottled, and flaked, some of the flowers being of good form. *Eranthemum pulchellum* was dwarf and good, and the new Fern *Nephrolepis philippinensis*, was in excellent condition.

Messrs. Veitch also sent a collection of fifty *Cyclamens* in small pots. The plants were remarkably well grown, and the colours rich and varied; a few of the whites being especially pure. Noticeable as towering above its fellows was a gigantic plant named *Model*; the flower stems of this variety are fully 18 inches in length and proportionately stout, the blooms also being very large.

Votes of thanks were most worthily awarded to Messrs. Veitch for these collections, and the Committee further recommended them as being worthy of a medal.

Cattleya bulbosa was exhibited by Mr. Hill, gardener to Sir W. Marriot, Bart., Down House, Blandford, and a cultural commendation was awarded; the plant was on wood and had fifteen flowers, and was considered to be a very superior specimen. *Masdevallia Davisii* in splendid health, the dozen yellow flowers being very effective, was exhibited by Mr. Murrell, gardener to W. Burnley Hume, Esq., The Hill House, Winterton, Yarmouth. This is one of the Chelsea seedlings which received a first-class certificate last year; since then the plant has greatly improved both in the size and colour of the flowers, and is a superior variety.

Mr. Green, the Botanical Nursery, Holmesdale Road, Reigate, exhibited a collection of succulent plants, for which a vote of thanks was awarded. Amongst these *Mesembryanthemum truncatellum* received a botanical certificate. These are very curious plants, as also were some miniature *Masdevallias* from the same exhibitor. The collection included *Echeveria metallica crassa elegans*, a promising variety with fimbriated leaves.

Messrs. Stuart & Mein, Kelso, sent *Rhipsalis pachytrichs*, its Cactus-like leaves being fringed with flowers; and Mr. Chambers, Westlake Nursery, Isleworth, sent seedling plants of *Hoya carnosa* with marbled foliage. The plants were not in bloom.

PAPYRUS ANTIQUORUM.

I was much interested in reading your remarks on the *Papyrus antiquorum*, as I had no idea it would live out of doors in our climate even during the summer. I am extremely fond of aquatic plants, and have a tank in my garden where several flourish well, and amongst them the beautiful *Cyperus alternifolius*, also the native *Cyperus longus*, of which family I believe we may claim also the diminutive *C. fuscus*, but I fear it is nearly if not quite extinct, unless Mr. Robert Parker of Tooting succeeded in discovering a few plants in a locality of which I gave him intimation that it had been found.

Some of the *Panicums* make striking and elegant additions to the summer flower beds. *P. plicatum* flourished well with me last year and flowered freely.

If any of your correspondents can furnish me with any additional names of aquatic plants I shall feel extremely obliged.—M. A. WALKER.

ROYAL HORTICULTURAL SOCIETY.—The Council recommend for the offices of President, Treasurer, Secretary, Committee-men of the Expenses Committee, and Auditors of the Society,

to be elected at the Annual Meeting on the 8th of February:—*President*, Rt. Hon. Lord Aberdare; *Treasurer*, Henry Webb; *Secretary*, Robert Hogg; *Expenses Committee*, William Campion, Henry Webb, and Vice-Admiral W. W. Hornby; *Auditors*, Conrad H. Pinches, James F. West, and John Lee.

MUSK AS A BORDER PLANT.

Nor nearly so freely is this odoriferous old favourite plant employed in borders as it ought to be. Being quite hardy the least possible amount of labour is needed in cultivation. For the sides of walks in partial shade, and especially in moist places, it is admirably adapted as a carpet plant, and it will fill the air with its refreshing perfume. It is one of the most popular of pot plants, and is equally at home in the cottage and conservatory. But cottagers and gardeners have not yet recognised its value as a border plant, or Musk beds would be as common as Mint beds.

In light dry soils and in hot situations, however, it does not flourish, but in strong and moist soil and in shady spots it luxuriates. Plant it in some damp nook where scarcely anything else will grow, or by the margin of the streamlet, and it will grow with a vigour that cannot be equalled by plants grown under glass. And how easily is it raised! A thousand plants can be had for sixpence with a little care in raising the seed.

The seed should be sown any time in the spring months. It will germinate at a low temperature such as a greenhouse or vinery affords, but a genial atmosphere is required to grow on the young seedlings. Where heat is sufficient the seed may be sown now and very strong plants will be had by May; but where artificial heat, say of 50°, is not provided for growing on the plants the sowing of the seed had better be deferred until February or March, when the natural and increasing heat of spring will make the greenhouse sufficiently warm for the young seedlings.

The seed is very small and requires a little careful treatment. The soil must be rich and very fine, and be thoroughly soaked before the seed is sown. Sow thinly, and lightly dust over it pure sand. Shade the pot or pan and place it in water, so that the soil is kept regularly moist without applying water to the surface. When the seedlings are large enough transplant them an inch or two apart in other pots or boxes, using rich soil, watering them copiously when established and growing, but until then somewhat moderately; yet they must never be dry. Gradually harden the plants off, and plant them out in May. It is only a question of room and boxes as to how many plants are raised, for few plants will grow more freely and satisfactorily. If showing signs of becoming drawn pinch out the tops. A cool frame after March is the best place to prepare the plants, the atmosphere of a house being frequently too dry.

When once established in the borders the Musk will push up each succeeding spring as thick as grass, and plants from a store bed may be drawn and transplanted like Cabbages in the months of April or May. Seed sown in the open ground will also germinate freely if the surface can be shaded and kept constantly moist.—*AMATEUR*.

CYCLAMEN SPECIES.

THE article of Mr. Robson (page 2) on the species of *Cyclamen* in ordinary cultivation opens up a subject which must be of interest to lovers of the plant. Without doubt there is some confusion in the names given to hardy sorts in gardens. The *C. europeum* of one is *hederifolia* of another, which latter name is given by Miss Annie Pratt as blooming from July to September; according to London it is a spring bloomer.

Are there really more hardy species in cultivation than *europeum* and *coum*? *C. europeum*, both pink and white varieties, seeds freely here, and I fancy has the same tendency to sport as the varieties of *persicum*. The bed containing them is annually dressed with leaf mould, which facilitates the burying of the seeds by the contracting stalk, yet only a few seedlings come up annually. Last season I gathered part of the seed from which I have some scores of plants that are yet too young to decide whether the apparent serrate, crenate, and entire leaves will be permanent. There is certainly some variety in the older plants self-sown.

I know of no plant more worthy of extended cultivation than the hardy *Cyclamen*. A bed once seen in full bloom, especially

the later bloom after the leaves have begun to come up, is not easily forgotten.—*R. C., Castle Gardens, St. Fagan's.*

ROSES GRAFTED ON THE BRIAR'S ROOTS.

IN answer to the inquiry of "AN OLD SUBSCRIBER" for more information on this subject, I may remark that any of the Briars will answer except the Sweet Briar. As to thickness, I use both large and small roots if they have but one fibre on

Fig. 13.

them. I cut them into convenient lengths. I like them best 5 or 6 inches long. The Rose shoots must be ripe and firm. The length is immaterial, but I generally have them the same length as the roots. If the root is a good one and strong I put on quite a strong branch. I sometimes use a piece of moss over the binding or a small portion of clay. If the Rose graft fits one side of the root that is all that is required. I use a small chisel to open the cut of large roots to insert the graft. If your correspondent will use a small tenon saw to cut the long roots into proper lengths he will find it much easier, as the Briar roots are very hard. Potting I think will not answer; the open ground is the best, planting firmly in fresh soil. A dung bed would root them quicker, but they suffer if not carefully hardened off. Whip grafting, as shown in figs. 13 and 14, also wedge grafting, figs. 15 and 16, may be

Fig. 14.

Fig. 15.

Fig. 16.

adopted as is most convenient, the stocks (b, fig. 14), being a portion of root having more or less of fibres attached, the scions (a) being well-ripened Rose shoots.—*J. C.*

"J. C." deserves the thanks of your readers for calling their

attention to this easy and certain mode of propagating Roses. I think however he is mistaken in supposing it has not been mentioned before, for I think this system of grafting Roses was alluded to by one of your late able coadjutors. I believe the late Mr. B. Fish, nearly twenty years ago, in giving a description of a garden he had visited, mentions a frameful of Roses grafted in this way. I regret not being able to name the place referred to or the exact date.

The talent of originating is not given to everyone, but all can imitate. I was then a young man, and since that time I have root-grafted not only Roses but a good many other plants that are somewhat difficult to propagate from cuttings. Amongst others I may name *Combretum purpureum*, *Ipomœa Horsfallii*, and *Luculia gratissima*. Apples on the *Paradise*, Pears on the *Quince*, &c., may also be worked in this way if it is thought desirable.

In conclusion, I think this system of grafting has probably been known and practised many years—probably centuries, but men in those days were less communicative; and besides, there did not then exist, in the shape of an ably-managed "horticultural press," the means of disseminating useful information.—H.

YUCCAS.

For many reasons Yuccas claim special attention. They rank under the head of plants with striking and decided foliage, peculiar and characteristic, contrasting well with other forms of vegetation. They are hardy, evergreen, adapting themselves to many circumstances, situations, and localities, and are not fastidious for the most part as to soil. They flourish at the seaside, in the heart of towns, and in the country, in either exposed or sheltered situations, grouped or as specimens. As an edging or boundary mark they have their own peculiar beauty. It is seldom one sees more than a single plant of Yucca in the generality of gardens, and that not unfrequently in a border or shrubbery classed with evergreens and Conifers, about the only position they seem out of place, yielding a somewhat disjointed harsh appearance. Yuccas are a great additional beauty to rockeries. In connection with terraces and as single plants placed right and left of a promenade they yield a substantial effect. Exposed to the dust and smoke of towns their foliage can readily be sponged and thus be kept clean and healthy. They remind one somewhat of the more tender *Dracenas* and *Aloes*. By the way, there are several proofs that one or two of the *Dracenas* are hardy, which should be taken advantage of more frequently.

Yucca gloriosa can readily be recognised by its stiff, upright, and substantial foliage, which is always prepared to remind the intruder of its unflinching presence. This is a magnificent plant for isolation on lawns, &c., or when massed in an irregularly raised and formed bed.

Y. recurva.—Perhaps the most beautiful of all, as it combines the dignity of *Y. gloriosa* with the peculiar grace of its arched leaves. The foliage attaining age has a systematic, pendulous, and recurring habit, while its unmaturing growth stands erect. This is suitable to precisely the same appointments as the former species, with a still further extension of appropriateness to vases and the like.

Y. flaccida.—The principal attraction of this species is in its free-flowering propensity, and its adapting itself to almost all soils. The whole strength would seem as if centred in producing its most elegant and magnificent blossoms yearly, so much to be envied by *recurva* and *gloriosa*. The foliage of *Y. flaccida* has at all times a pitiable appearance, turned and twisted by every gust of wind. If hospitals were provided for sickly plants it might well be taken for an outdoor patient by those not conversant with its natural habit.

Y. filamentosa.—The chief drawback of this species is seemingly its daintiness as to soil. In the black sands of Surrey it is truly charming, and I question if it would not grow in many places where it is now not seen. The principal feature in this plant is the thread-like fringe that borders its leaves. The foliage though beautiful can scarcely compete with the more noble *Y. gloriosa* and *Y. recurva*; but here again its freely-produced flowers are compensatory. It is no uncommon occurrence for single plants to produce three or more spikes of blossom, and, moreover, they occasionally bloom as late as September and October. I have no doubt that the blooming season may be retarded by breaking-off the crown of the bud when it first shows itself; it thus produces blossoms on a short stalk, and tends to encourage another spike to be thrown-

up later in the season. However, this plan would only be desirable in limitation, as the striking beauty of the Yucca flower is in its predominance over its neighbours. This species I more especially suggest as an edging to walks and the like. I could speak enthusiastically on an effect thus attained under my direction, but I cannot bring to mind having seen it similarly brought to bear anywhere else.

I would urge the extended and more general growth of the Yucca, of which the foliage and flower at all times will not fail to yield due gratification, whilst its adaptability to circumstances claims for it a universal recommendation.—HENRY COOPER.

RANGEMORE HALL.—No. 1.

THE SEAT OF M. T. BASS, ESQ., M.P.

SOME of the gardens of England are remarkable for their ornamental features, for their picturesque sites, and for their elaborate and artistic treatment from an æsthetic point of view. Others are noted for their genuine gardening excellencies, their fruitfulness, and usefulness in supplying the household wants of their owners. In most gardens, however, these distinctive features are combined, one or the other predominating according to circumstances and special requirements. At Rangemore there is a blending of the useful and the ornamental, the former being in the ascendant, yet the operations are so extensive, the management so good and systematic, and the means so complete, that there is here, as in many other instances, "beauty in utility." Besides evidence of able supervision on the part of the gardener this good and well-appointed garden bears impress of the ownership of a gentleman liberal and with a disposition to do all that he undertakes in the most complete and thorough manner. Mr. Bass, therefore, in conducting his extensive establishment, has become a patron of horticulture by the comprehensive scale of his gardening operations and by the ungrudging means afforded to perfect the work in the several departments.

Rangemore is situated about five miles from Burton-on-Trent, on the high ground skirting Needwood Forest, which is the property of the Crown. The mansion is on Crown property, the appurtenances being on the estate of Mr. Bass. The edifice is very spacious and is an imposing structure, overlooking an undulated country of park-like scenery. The grounds, or the ornamental portion of them, are not extensive but are a skir, as it were, of the Crown property, which stretches away from the principal frontage.

The gardenesque element of Rangemore is, I understand, likely to be extended, for, notwithstanding the ownership of the soil, Mr. Bass is contemplating considerable alterations and improvements. Mr. Bass's ideas of beauty are not, however, shapen in hard, formal, and artificially curved lines. He cannot endure the mutilation of nature which is by some called artistic treatment, but he enjoys the simple easy freedom of irregular clumps of Hawthorn, semi-wild bowers of Honeysuckle, huge masses of the Dog Rose and Sweet Briar, and an intermingling of native trees and flowers. The natural graceful beauty of Rangemore must, in the spring, when the Thorns are adorned with their snowy flowers and the air is laden with the perfume of Roses and Honeysuckles, be extremely enjoyable, and likely to suggest regrets that our native trees and flowers are not more generally permitted to dispense their charms in their own effective manner.

A broad carriage drive leads to the mansion, skirted by a stately sweep of lawn, which is bounded by trees and shrubs, left, in a great measure, to their own natural habits to mingle together in a free and easy manner, which is appropriate to the nature of the place and its surroundings. Yet the grounds are not destitute of art, but its touches are very gentle. As will be seen by the accompanying plan there is a terrace walk along the principal front of the mansion which, at intervals, contains raised beds, supported by stonework and planted with flowers. Near the extremity of the walk is the flower garden, which fronts the conservatory, this structure being in connection with the mansion. The flower garden is not extensive, and is simple and graceful in design. It is intersected by gravel walks, and as standard Roses are employed in connection with the usual bedding plants the garden is sweet as well as gay. This design is figured as being adaptable to a large or small garden.

The garden is gay also in spring as well as summer, and is not barren and devoid of attraction in the winter. As soon as the summer plants are removed the beds are promptly filled

Fig. 17.—RANSMORE HALL—PLAN OF THE FLOWER GARDEN.

with dwarf shrubs and spring-flowering plants. These plants are not puny examples dotted in here and there, but the Daisies, Polyanthus, Myosotises, Pansies, &c., are stout well-

grown plants, and planted sufficiently close to cover the soil at once, and are thus in the best condition to give a full and early display. Beds thus filled and supplemented with dwarf

shrubs have a far more cheerful effect during the winter than has bare soil, however neatly it may be levelled, and however trimly the beds may be kept. Spring gardening is, unfortunately, too often only half done, and the system is condemned because it is not properly carried out. It should be done well or not at all, and it cannot be done well without a considerable expenditure of time, which can be ill afforded in a majority of gardens and with the staff of labour which owners only feel justified in providing. Spring gardening involves special and extra labour, and where this is not afforded it ought not to be expected to be carried out. At Rangemore it is done well, and the beds are as enjoyable in early spring as during the summer and autumn months.

The conservatory is spacious but not ornate. It is principally enjoyed by Mrs. Bass, who is, unfortunately, an invalid. It contains tree Ferns and the usual decorative plants, but it is principally noteworthy for the fine Camellias, which, without any forcing, commence flowering in October.

The grounds adjacent the conservatory are appropriately ornamental. The lawns contain a profusion of Rhododendrons with some admirable Conifers. Cupressus Lambertiana is especially noteworthy for its towering form; and Wellingtonias and Cedars of Lebanon, Cryptomerias, &c., are represented by fine healthy specimens. The grounds also contain choice deciduous trees, and some glimpses through this foliage of hill and dale, grass and water, are worthy of the artist's pencil.

From the mansion, and at a distance of about half a mile, is the handsome church, erected and endowed by Mr. Bass. The approach to this edifice is by an avenue of Wellingtonias and Cedars of Lebanon, which are planted in considerable numbers, and, although the soil is of a strong clayey nature, the specimens are in perfect health and colour, and especially where not exposed to a strong sweep of wind. When planted thinly, and in exposed positions, trees of this nature seldom progress favourably, let the soil be ever so well prepared, and it is always advisable to provide shelter by a close planting of free-growing trees as "nurses," and to be removed as their services can be dispensed with. By such aid choice and valuable trees will attain a greater size in ten years than they would in thirty years if planted unsheltered.

But while a great deal may be found to admire in the ornamental department of Rangemore, and much instruction be gathered, especially from its semi-natural features, yet it is the garden proper—the walled enclosures, and the work that is done in them, its extent and thoroughness—which are the most remarkable features of this fine place.

The walled gardens, which are on Mr. Bass's private estate, are six acres in extent, and contain glass structures of such size and numbers as are seldom seen in a private establishment. They consist of forty houses besides pits and frames, and an idea of their extent will be formed from the fact that they contain three miles and a half of hot-water pipes. These pipes are heated by three boilers at an annual cost for fuel of £700. The forcing of vegetables is carried on on an extensive scale. Seakale is provided in October; Asparagus in November, £70 worth of crowns being forced annually, the best being prepared in France and supplied by Messrs. Veitch & Sons; green Peas (a few) are had at Christmas, French Beans nearly always, also Mushrooms and salading.

Fruit is also extensively provided for Mr. Bass's English and Scotch establishments. The work of fruit-packing is of no trifling character, it not being unusual to send to Scotland 7 or 8 cwt. twice a week during the autumn months. This, after travelling five hundred miles by railway, fifty by water, and twenty-five by land, invariably reaches its destination in good condition. Grapes are packed in stout glazed brown paper, each bunch forming a cone; the bunches are packed with base and apex interfitting, and frequently arrive with little or no loss of bloom. This stout paper and wadding are the only materials used in packing. Boxes are made convenient for the different kinds of fruit, and these are placed in hampers, packed in dry leaves, so that injury by jolting and shaking is reduced to a minimum. The paper has a perfectly glazed and smooth surface, and is found to disfigure the Grapes less than any other kind of envelope.

The garden, or a great portion of it, is comparatively new, and one might fancy that the site had been chosen on the principle that as it would do for nothing else it might do for a garden. The ground is so irregular that it would be difficult, if not impossible, to have worked it by the plough; and the natural soil is of that hard, heavy, barren nature that Messrs. Luckhurst and Taylor have written about. If either of them

have a more ungenial staple than the soil at Rangemore they are sincerely to be pitied. But bad soil brings out good qualities, not of fruit and vegetables merely, but skill and energy on the part of the culturist. The soil is here so inert, and worse than inert, that sites for fruit borders have to be excavated and made entirely of new soil. Even Asparagus will not grow unless the beds are made entirely of new soil, for the natural soil when in contact with the shoots causes them to rot off as if poisoned. A soil of this nature can only be made fertile by a considerable outlay of capital and skill. Fire is the only real renovator, and fire has been here applied. It is a matter of manuring the ground with coals, and is expensive, but it is really the most economical mode of treatment. By burning, and persevering work, many crops now grow luxuriantly which otherwise would not grow at all. As an instance of the extreme irregularity of the ground and the soft and unstable nature of the soil, the foundation of the garden walls where they crossed the hollows had to be put in 15 feet deep. Difficulties have, however, only been regarded as "things to be overcome," and the lofty and substantial walls are firm, and are being rapidly clothed with trees. The condition of the soil is totally changed, and is profitable, and the extensive glass structures are not in better condition than are their contents—the Vines, Pines, Peaches, &c., and plants. But as has been said, the whole of the fruit borders have been made of new soil; and when we look at their extent both under glass and in the open garden, and are informed that the soil has been brought from a distance of five to six miles, we in some degree realise the stupendous nature of the work, and cannot but be surprised at the present completeness of the gardens and of the general excellence of their many productions.

It is not possible, neither is it necessary, to particularise the condition and contents of every house, for 100 yards of Peach houses are only the counterpart of another; I shall, therefore, in my next communication only notice in a general way a few prominent features of the place, pausing at anything which is worthy of mention, and especially as affording a measure of instruction.—J. W.

HOW NEAR TOGETHER SHOULD THE RASPBERRY BE PLANTED?

ALL writers, I think, give 8 by 8 feet as the proper distance. Visiting plantations this past summer, I found one where the plants were in rows of 8 feet apart, but were from 16 to 18 inches apart only in the row. The grower only permitted one cane to fruit, while one cane only was grown for fruit of the coming season. He certainly had the largest and finest berries that I saw anywhere of the same variety, the Franconia, and he told me that his expense of picking was less than when grown three or four stems to hill, with as many more of canes for next year, and the extra price for these large berries more than balanced the account. His practice is to pinch the top of the young cane of this season when about 1 foot high, then again when it had made a growth of 6 inches, then again at 6 inches, until it is 3 feet high. His pinching-back was an easy and quick job, and left the stems with lateral leaves resembling little trees, and they stood so firm that no wires or stakes were needed.—F. B. E.—(Boston Cultivator.)

[It would be well for this experiment to be tried on a small scale to test its value in this country; we have not before heard of the practice of "summer pinching" having been applied to the Raspberry.—Eds.]

THE HOLLY.

[This is the conclusion of Mr. J. Kentish's communication commenced in our last number.]

THE Greeks named Holly *Agria*—that is, ferocious, on account of its prickly leaves. The Romans similarly called it *Aquifolium*, from *acutum*, sharp, and *folium*, a leaf. Bauhin first named it *Ilex* on account of the resemblance of its leaves to those of the *Quercus Ilex*, the true *Ilex* of Virgil. Linnaeus adopted the name of *Ilex* for the genus, and preserved the name of *Aquifolium* for the most anciently known species. The name Holly is probably a corruption of the word "holy," as Turner in his "Herbal" calls it Holy and Holy Tree, probably from its being used as a decoration at the holy time of Christmas, not only in houses but in churches. The German name *Christdorn*, the Danish name *Christorn*, and the Swedish name *Christorn*, seem to justify this conjecture. I have also

found the reference to the Holy Bush and Yew speaking of Christmas times; beside, also, it used to be spelt "Holy" years back. In England Holly also bears the names of Hulver, Hulvere, and Holme.

Dr. Prior says, "Holly or Holm is on the eastern border called Hollen, the old form of the word, and that from which *holm* has been formed by the change of *n* to *m*, as Lime from Line; A.S. *hollen* or *holegn*, a word derived from L. *Ulex*, which in the middle ages was confused with *Ilex*, the Holm Oak of the ancients, whence the adjective *uigna*, and with the prefixed aspirate, *huligna* and *holegn*. The form *Holly* will have been the more readily adopted, from the branches of this shrub being used for Olive branches, and strewed before the image of Jesus, in certain solemnities of the Church that represented His entrance into Jerusalem. Thus in Googe's *Naogeorgus*—

"He is even the same that, long ago,
While in the streets He rode,
The people mette, and Olive bowes
So thick before Him strode."

Hulver is a corruption of the French for Olive, *Olivier*.

There are several distinct varieties, and very many shades of each variety. The following are some of the kinds of common Holly—Narrow-leaved, Broad-leaved, the High-Clere, the Thick-margin-leaved, the Laurel-leaved, the Oiliated-leaved, the Smaller, the Recurved, the Serrated, the Curled, the Fierce or Ferociously-spined-leaved, the Thick-leaved, the Aged or Spineless, the Variegated-leaved, the White-edged-leaved, the Gold-edged-leaved, the White-spotted-leaved or Milkmaid Holly, the Gold-spotted, the Silver-blotched Hedgehog, the Gold-blotched Hedgehog, the Yellow-fruited, and the Gold-fruited. The largest Hollies in Kent, Buckingham, and Surrey grow in loam on chalk. Holly likes a free loamy soil, and attains its largest height in rich sandy loam.

The Holly tree has been admired from the earliest periods. In former times it was largely grown for hedges. Evelyn's Holly hedge at Saye's Court, Deptford, 400 feet long, 9 feet high, 5 feet in diameter, has been celebrated ever since the time of Bay—i.e., about two hundred years ago. There are also some hedges in France over two hundred years old. Evelyn observes, "I have seen hedges, or, if you will, stout walls of Holly, 20 feet in height kept upright, and the gilded sort budded low, and in two or three places one above another, shorn and fashioned into columns and pilasters architecturally shaped, and at due distance; than which nothing can be more pleasant, the berry adorning the intercolumniations with scarlet festoons and encaipa." There are several noted Holly hedges in Scotland. The only objection to Holly as a hedge is its slow growth. When obtained it is the best hedge and the least expensive to maintain.

The wood of the Holly has peculiar properties. It is white, except in the centre of old trunks, there brown. It is very useful in joining, cabinet-making and turning, mathematical instrument making, wood-engraving, for whip handles and walking sticks, also for veneering; and though the wood is naturally so white, when dyed it makes a good substitute for ebony. It is not grown enough to make it much used as a veneer. As in Mistletoe, the bark affords birdlime. The decoction of the bark has been used to calm a cough. The berries are purgative, six or eight cause violent vomiting. Though the birds, especially the thrush and blackbird, feed on them they are considered poisonous to men.

The custom of placing evergreens in places of worship prevailed before the introduction of Christianity, and in proof of which reference is made to texts of Scripture, particularly in Isaiah and Nehemiah, as having reference to it; but the evergreens originally made use of were the branches of the Pine, Fir, Cedar, and sprigs of Box. Holly appears to have been first used for this purpose by the early Christians at Rome and was probably adopted for decorating the churches at Christmas, because Holly was used in the great saturnalia which occurred at that period; and it was the policy of the early fathers of the Church to assimilate the festivals of the pagans and Christians as closely as could be permitted in their outward forms. It was customary among the ancient Romans to send boughs of Holly during even the saturnalia, as emblematical of good wishes, with the gifts they presented to their friends at that season, and the Holly became then to be considered as an emblem of peace and good will. It was for this reason, independently of any wish to conciliate the pagans, well adapted to be an emblem of the principal festival of Christianity, which inculcates peace and good will to man.

Whatever may be the origin of the practice, it appears to be of very great antiquity. In England perhaps the earliest record of this custom is in a carol in praise of the Holly written about four hundred years ago, in the reign of Henry VI. Stowe in his "Survey of London," published in 1598, says that in his time every man's house, the parish churches, the corners of the streets, conduits, market cross, &c., were decorated with Holme [Holly], Ivy, and Bays at Christmas.

The Holly is of long duration, as we read of a tree in Tusculum 80 feet in circumference, with ten branches of such magnitude that each might pass for a tree. This single tree alone resembles a wood. Cole, in his "Paradise of Plants," says he knew a similar tree. The owner cut it down and caused it to be sawn into boards, and made himself thereof a coffin, and left enough to make his wife one too, both parties being very corpulent. There are Hollies in Frensham in Surrey some 60 feet high. Evelyn mentions some large Hollies near his place at Wootton in Surrey, in the neighbourhood of which was once a fort called Holmsdale Castle, from, as he supposes, the number of Holmes or Hollies which once grew there. The names of Holmsdale, Holmwood, and Holme Castle occur in various parts of Scotland, and are generally supposed to have been applied in consequence of the abundance of Holly at these places at the time they were named. In 1862 Mr. Mayhew made a calculation that about 50,000 bunches of Holly and 50,000 of Mistletoe were sold in London every season; and that £200 worth of Holly was required only for the sprigs to be stuck in the puddings in the metropolis.

COVERING VINE BORDERS.

AFTER what has been written on this subject most cultivators will doubtless prefer having the roots of the Vines producing late-keeping Grapes in inside borders; and if the roots or a portion of them are outside, they will feel safer if the surfaces of such borders can be protected from heavy rains in the autumn and winter. That an influx of moisture to Grapes after they have ripened is detrimental to their keeping is pretty generally admitted; but much, as Mr. Taylor has reminded us, depends on the temperature and atmosphere of the house, and Mr. Walker adds very convincing evidence of the importance of this point. He has told us of his failure to preserve Grapes where the border was covered with glass, when he was compelled to have damp soil turned up in the house.

There is little doubt that a dry border and a damp atmosphere is more prejudicial to the keeping of Grapes than is a wet border with a dry atmosphere. We seldom find Black Hamburg Grapes hang better than those in orchard houses where the Vines are trained very thinly and where a constant circulation of air is afforded, not for the Vines but for the trees. Very commonly in such houses do Black Hamburgs hang plump and fresh until January: an advantage to their thin training and full light and air-exposure is that the Vines are generally planted inside and trained up the pillars.

That Grapes have frequently been preserved until the present time, when the borders have not been covered, is undeniable, and "W. E." has quoted a case in point where the house in addition to the Vines contained plants which had to be watered occasionally. I have preserved Grapes under similar circumstances by bestowing great care on the temperature and ventilation, but I found the work much more easy after I obtained shutters for the borders.

That heavy autumnal rains facilitate the decay of Grapes I found out by accident. The down pipe conducting the water from the vinery became obstructed, and before it could be rectified the border near it became thoroughly saturated, and the Grapes on the three Vines which were so much soaked decayed much more rapidly than those on the other Vines in the same house.

I have found too that when shutters are provided they should, if much rain fall, be used early in the autumn, and not withheld until the Vines have cast their foliage. With heavy autumnal rains, when the foliage of the Vines is more or less in an active state, much more water is conveyed to the fruit than by a similar weight of rain after the foliage has fallen. Indeed I am not certain that the Grapes which are cut and the stems inserted in bottles of water do not receive as much moisture as do those on Vines in uncovered borders and after the foliage has fallen.

During late years I have covered my borders early—that is, considerably before the Vines have cast their foliage, and have

found the advantage of so doing by the better keeping of the Grapes. I have indeed, for the purpose of experiment, partially covered a border, leaving the other part exposed, and found the covering decidedly beneficial.

Previous to placing on the shutters I have been careful to note that the border was not dry, for to cover up a border in a dry state and to keep it dry for six to seven months is to injure the constitution of the Vines. Mr. Walker with his glass coverings appears to be specially careful on this point, and finds it necessary to water the borders periodically before finally removing the lights which shelter them.

The soaked Vines referred to as injuring the keeping properties of the Grapes did not injure the Vines, for I was surprised to find them in the following season producing the finest Grapes in the house. Coverings, therefore, while being useful must not be abused; their employment must be governed by the rainfall, the drainage, and the retentive or percolative nature of the soil—or, in other words, I attach more importance to the intelligence and sound judgment of the man than to the mere rain-proof nature of the covers.

Just as the keeping properties of Cherries and Gooseberries are impaired by heavy rains in summer, so are Grapes injured by heavy rains in autumn—that is, when the Vines are in full leaf, and summoning the roots to send them up all the water they can absorb. I therefore cover according to circumstances, sometimes in September and at other times not until November, and the covers have decidedly afforded me great assistance in prolonging and preserving late-hanging Grapes.

As to the nature of the skins of the Grapes influencing their keeping, my experience is in favour of a well-finished skin. What I mean is, that berries deficient in colour have thinner skins than those which are well-coloured, and the latter keep the best. I have occasionally cropped the Vines under my charge very heavily—too heavily, as some uncoloured bunches have proved. These have had thin skins and would not keep. As a rule, the lighter Vines are cropped the stouter is the foliage and also the skins of the fruit; and I have found such fruit on such lightly cropped Vines to keep the best.

I observed also that the thin-skinned Gooseberries during the deluge of last summer were the first to decay; the thicker-skinned varieties alone surviving the watery ordeal to which the crop was subjected, and in some districts almost totally destroyed.

Lightly cropped Vines, well-skinned bunches, and fully-coloured berries I prefer for late-hanging Grapes; and sheltering the borders as soon as heavy rains fall in the autumn, and paying due regard to the temperature and atmosphere of the house, are, I consider, important items leading to success.—A NORTHERN GARDENER.

NEW BOOK.

Potatoes: or How to Grow One Thousand Pounds of Potatoes from One Pound of Seed. By JAMES PINK. London: William Ridgway, 169, Piccadilly.

[The following review of this sensational pamphlet is from the pen of an experienced Potato-cultivator, and one whom we know has no prejudices against new vegetables as such, of which proof is afforded by the tone of his article on "Peas New and Old," which we published last week.]

This is a pamphlet of seventeen pages of widely printed matter. In half a dozen of these pages the author describes the mode of culture which he adopted in raising a trifle over two-thirds of the standard weight from 1 lb. of seed (diseased tubers not being weighed), the remaining pages being devoted to a recapitulation of the conditions of Messrs. Hooper & Co. in offering certain prizes, a commentary on the proceedings in connection with that Anglo-American enterprise, a little philosophy, and some sentences of complaint in the "interests of truth" and for the "benefit of horticulture."

The object of the author is avowedly remonstrative, for he states that he "had not the remotest idea" of writing the pamphlet until "discredit was thrown on the successful competitors by the *Gardeners' Chronicle*" in the following report:—"We should not be surprised if the course taken by the Judges does not lead to a considerable amount of discontent; but for the present, at all events, has closed one of the greatest horticultural farces ever put before the public, and it is difficult to perceive how, by any possible means, this competition can ever be of any benefit to horticulture." Now, as to the "dis-

credit," that clearly refers to the scheme, and not to the man who carried it out; as to the predicted "discontent," the pamphlet proves its existence, while it fails to prove that the competition will or can "benefit horticulture."

In the "interests of truth" we may give Mr. Pink the fullest credit for the legitimate way which he carried out his experiments. We accept his weights to the last ounce, and recognise his cultural skill in producing his sensational crop. He reveals a good knowledge of Potato culture by deeply working the ground and adding to it the following manures:—"Ten bushels of wood ashes, ten bushels of leaf mould, one bushel of soot, 4 lbs. of sulphate of ammonia, 6 lbs. of sulphate of soda, 10 lbs. of nitrate of soda, and 10 lbs. of sulphate of potash," to eight and a half perches of ground, further dressing with "50 lbs. of superphosphate of lime previous to the final earthing-up of the plants."

The pound of Snowflake was cut into eighty-two sets, and Eureka into 121 sets, a further pound of Brownlee's Beauty being cut into forty-three sets to occupy the remainder of the ground. The sets were planted on April 3rd in drills 3 feet apart, and the same distance between the sets. On August 6th the crop was taken up, the Eureka produce weighing 672 lbs.; Snowflake, 405 lbs.; and Brownlee's Beauty, 290 lbs. The 3 lbs. of seed thus yielding, not 3000 lbs., but 1367 lbs. of produce, or, including the diseased tubers, the average may be put as half the standard weight, or 500 lbs. per 1 lb. of seed.

Twenty sets of the latter sort were planted on inverted flower-pots (24's) sunk at the requisite depth, as an experiment in drainage, and these produced half a pound per hill more than those planted in the ordinary way.

Now, in the "interests of truth" all this may be at once accepted as correct. As a curiosity it is novel, but as a crop of Potatoes it is easy to prove that it is of no real "benefit to horticulture," because practically it is not a large but, considering the high culture of the ground, really a small crop, and for any real benefit that it can confer (except to those immediately interested) it is practically worthless, and adds nothing whatever to the cause of "the food supply of the country."

This is an important matter, and must not be treated in a superficial manner. "Anything" it has been said (but not in the pamphlet), "can be proved by figures," but figures are sometimes fallacious. Let us see where they lead us in Mr. Pink's own example of practice.

By sinking flower pots he obtained an increase of half a pound per root. According to that, if the plan had been carried out throughout the ground, Eureka would have produced 730 lbs. instead of 672 lbs., and the aggregate bulk would have been nearly 1500 lbs. instead of 1123 lbs. But let us go further. If Eureka had been so planted to the extent of an acre the pots would have increased the value of the crop at 3s. 6d. per pound (the selling price of the tubers) by £420. The pots could be delivered on the ground at 8d. each, and they could be planted for 1d. each. At the rate of increase and price quoted each pot would leave a profit of 1s. 9d., and would bring up the crop of Eureka to a value of upwards of £4000 per acre. All that on paper looks wonderfully like benefiting horticulture, but in practice there would be slight drawbacks; the value of the produce would not (happily) be sustained, and perhaps every pot would not bring its additional half pound. At any rate, advantageous and profitable as the pot plan and eye subdivision of Eureka at 3s. 6d. per lb. may appear by rules of arithmetic, not many cultivators will adopt it in producing crops for the markets, and the experiment remains empty—a novelty conferring no benefit, and viewing it in regard to the "food supply," it would make that food terribly "dear meat."

In seeking to prove the great public value of the system detailed in the pamphlet, the author takes his stand on the old aphorism of "making two blades of grass grow where only one grew before," and hence he concludes that "the competitors have done good service to horticulture." Let us test the soundness of this premise. The "two blade theory," like other two-edged blades, cuts both ways. Before the grass can be beneficial it must possess the quality of being "good to eat." Most dwellers in the country have seen two, and many more than two, blades of grass grow where only one grew before, and they have also seen the cattle avoid these rank knolls which have been scattered over the pastures, even when the animals have been starving for want. Where that is seen it is regarded by the agriculturist as the result of neglect, and betokens bad management, because the elements of the

soil and manure are wasted, and the additional grass represents loss instead of profit.

Now, not one word is said in the pamphlet on the good quality of the American Potatoes, and, for aught that is said to the contrary they may be "Boss Tweeds," and have taken more than they gave; but the author does state that he grew "forty sorts," and that "Eureka was the first to be affected by the disease (on July 21st), and next Snowflake, and then Brownell's Beauty." That is not a satisfactory result, for if two Potatoes have been made to grow where only one grew before, the increase is a loss, and not a gain, unless the produce be sound and of good quality.

The value of the varieties are assessed according to their number of eyes, Eureka heading the list with 121 eyes. But is that any real gain? Is it not rather a substantial loss? The superiority of a tuber is generally expressed as having "few eyes;" but here for the first time in Potato history "many" eyes becomes a virtue. It is a virtue, however, that ordinary observers and impartial judges—those whose first study is the interest of the community—will not and cannot recognise, and hence the unanimous verdict of the visitors in regard to the many-eyed monsters exhibited at South Kensington—a verdict which may be truthfully entered in three words—words that were repeated again and again throughout the corridor—"Fit for pigs."

The double-produce theory thus falls in the essential point which could give it value; but it fails also irrespective of any conditions, for in the experiments recorded two Potatoes have not been made to grow where only one could be before produced, as hundreds of cultivators know, and all may prove during the ensuing season.

At the given rate of produce the weight per acre would be under 12 tons. Why, that is not at all an uncommon weight, and is in fact frequently equalled in the Potato-growing districts of Lincolnshire and Yorkshire in field culture under simple plough tillage.

But let us take a parallel case. We take the produce as stated as averaging nearly 6 lbs. per hill (square yard); the cost of the seed being 10s. 6d. Now take an equal number of sound sets of Victorias, Regents, or Dalmahoyas. These at an average weight of 2 ozs. each may be purchased for 1s. 6d. Prepare them well, and plant in similar ground, similarly manured, and the crop, instead of being 6 lbs. per square yard "fit for pigs," will be at the least 12 lbs. per square yard, and fit for princes. Which mode confers the greatest "benefit to horticulture," and does most for the "food supply of the country?" In the one case we have a greater amount of valuable produce at small cost; in the other a lesser amount of questionable produce at great cost.

The Potato is a staple article of food, and the question of its supply and improvement must be subservient to ordinary requirements and in accordance with the ordinary and most economical modes of production. If it cannot stand this test a new introduction is only an innovation—a novelty, and not an improvement of real worth and national value.

If Mr. Pink's pamphlet is productive of good, it will be by stimulating inquiry and in fostering deeper thought amongst cultivators as to how they can best, and in the most practical manner, produce the greatest supply of superior produce at the least cost. That will not be by performing a surgical operation on the eyes of Eureka.

But, it may be urged that all new Potatoes must have a trial. True: the Americans have had a trial, and what is the result? Let those who have to purchase in the markets of cities and towns answer. Is the standard of quality improved in the greengrocers' shops? Is the supply in London better than it was ten years ago? nay, is it not worse? Are there no "Early Roses" sold to the multitude as "Flukes," and at Fluke prices? When an affirmative reply must be given to the latter questions, and a negative to the former, then the improvements have shown themselves in a singular manner, and after a period of trial has been sufficient to create an effect.

It is unfortunately pretty clear that the foreign novelties have been over-estimated. They are for "show" rather than for real service, and it is not a "benefit to horticulture" to exalt them above their sphere and to impart to them a value that they do not possess.

Managers of Potato shows, and the judges of those shows, need to exercise great discrimination, or they will fail in their purpose of improving the Potato. That is their aim, and it is a laudable one; but at all great Potato gatherings prizes are

awarded to dishes that would not be permissible on a gentleman's table. The prizes may be given to the "best" in the classes, but that best represents too often a low type of quality. That many new sorts are imposing in appearance is willingly admitted, and that others are good is not disputed, and especially those of our countryman Mr. Fenn. The cultivation of new sorts gives pleasure, and the exhibiting of the tubers affords an enjoyable field day to the growers and the public; but exhibitions can only be made instructive by special care and discrimination, lest a fictitious value be given under the stamp of authority to sorts that cannot eventually serve any useful purpose.

As to offering prizes of the nature of those championed by Mr. Pink in his pamphlet, they can no more "benefit horticulture" than would prizes for the greatest weight of Cabbages from an ounce of seed, where Robinson's Champion Cattle Cabbage would inevitably triumph, while Early York and other small sorts of superior quality would have to hide their "diminished heads," and be dishonoured.

In conclusion, let it be noted that this has, like the pamphlet which suggested it, been written solely in the "interests of truth" and for the "benefit of horticulture."

NOTES ON VILLA AND SUBURBAN GARDENING.

FORCING SALADS.—The increasing demand for the different kinds of salad plants at all seasons of the year is one of my reasons for making a few remarks upon some of the best and most convenient modes of raising them for use; and the next is, that as in most instances the more substantial ingredients of the salad bowl which are grown in summer, such as Lettuces and the different sorts of Endive, will by this time be nearly exhausted, that it is time to think of supplying their place with others in a forced state. I will therefore begin with

Chicory.—This is a root much like a Carrot in shape, and should be grown in rich ground in summer, taken up in autumn, and stored up in a similar manner to other roots; but the crowns ought not to be cut off so closely as to interfere with their growth, as it is from these that the produce comes when forced. For forcing the roots may be planted in soil on a bed of heating material, also in any heated house or frame; or for an amateur perhaps the most convenient way would be to pot a few roots, say a dozen in each pot, and place them in the forcing house, turning another pot over this to keep them dark, which in all cases must be done in order to have the leaves properly blanched. One inexpensive mode is, when a good heap of leaves can be brought together, to dig a space sufficiently large, in the middle of it put some soil in, and when the heat is rising moderately plant the roots. Bank up the leaves high enough on each side to support a covering—this may be a thatched hurdle—and afterwards covered with leaves or rough litter to keep the heat in. Than this there is no better plan for raising Chicory. Violent heat is to be guarded against, for this root is easily excited into growth. Next in popularity are

Radishes.—These require heat if wanted early, but they also need light and to be grown near the glass. It is not, however, necessary to make up a bed specially for them, as they being soon over may be grown with other crops, such as Early Horn Carrots, Potatoes, or even with Asparagus; when these crops are planted sow the Radish seed among them and lightly cover it; the Radishes are soon up, and with a little care are quickly in for use. Wood's Early Frame, the French Breakfast, and Oval-shaped Scarlet are desirable sorts; the scarlet and white Turnip Radishes may also be relied upon. If a large and constant supply of Radishes is required it will be necessary to make beds on purpose for them at this early season.

Lettuces.—Though these are not generally forced they are so very important in a salad that it is necessary to take every possible means to obtain them at all seasons. I am now using Wheeler's Tom Thumb, a Cabbage Lettuce, and the Siberian Cos, which were sown late and have been planted out under temporary covering and protected from frost, and a frameful of Bath Cos is in store for succession. To succeed these another crop must be sown under protection as soon as possible. The shelter afforded by a cold frame is all that is required. The plants must be grown thinly and advanced steadily, or they run up so delicate as not to produce hearts and are therefore worthless; and again, in every garden there ought to be a store planted out under walls. I always make it a practice of raising a good number of plants of the small Cabbage kind, and I have always proved them useful.

Mustard and Cress is ever in demand, because if not generally employed in salads it is used by itself. It can be raised in nearly any place where there is a temperature above 40°. The seeds should be sown regularly over the surfaces of shallow boxes or pans, and then pressed into the soil by some flat instrument and not covered, but be kept watered; the seeds soon germinate even in a dark place, when the pans can be brought

to the light, and in a week or two their produce will be fit to eat.—T. RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

Owing to the severe frost and snow it has not been possible to do any out-of-door work, but the men have been cutting out some of the short branchlets to which we have previously alluded, to support the Strawberries when ripe. They are tied up in bundles, and placed in a dry place to be ready for use when required.

In the gardens of amateur fruit-growers of small means, who do their own gardening or who cannot afford the expense of a skilled gardener, a frequent blemish is to be found in the unskillful management of the fruit trees on the garden walls. One finds a few of all sorts of fruit trees, but none of them giving any real satisfaction. The worst managed of all are the Peaches and Nectarines. The walls are generally from 6 to 9 feet in height, and the trees are trained so that not more, perhaps, than one-third of the wall is covered with bearing wood.

Now unless the amateur has plenty of spare time and is an enthusiast in fruit culture he ought not to grow Peach and Nectarine trees. They are the most difficult to manage of all, principally because of their liability to be attacked by insect pests. As soon as the leaf buds open in early spring they are attacked by the Peach aphid, which very soon spreads over the trees and causes the leaves to curl; the experienced cultivator will destroy this insect pest before the leaves are injured, by careful washing with soft soap dissolved in weak tobacco water. I have seen Peach trees so badly attacked with aphids that not only was the crop of fruit spoiled for that season but also for the next, and the trees so much injured that it would require several seasons of the best management to restore them to good condition. If the trees escape the attacks of aphids in the spring they are very likely to fall a prey to red spider in the autumn. This pest will begin its attacks as soon as the hot weather sets in. It is easily detected by the appearance of the leaves, which show a lighter green in blotches on the upper surface from the spider sucking the juices from the under sides. Spider may be kept in check by the trees being syringed freely once or twice a-day in hot dry weather. All this is well understood by the trained gardener, but the amateur has not often the time to spare, nor does he care for so much syringing. Plum and Cherry trees also suffer from insects peculiar to the different trees, but they are usually free from red spider, and are also much more hardy than Peach trees.

The most useful hardy fruit for an amateur's garden is the Pear, not because the fruit is of more value than Plums or Cherries, but because a succession can be had from July until March or April. The Pear is also equally well adapted for low or high walls. The best form to train the trees is the horizontal, and when the walls are of brick the work of training is very simple. Let us take a tree one year old. It has one strong single growth: this is cut back to 14 inches from the surface of the ground. When the tree starts in the spring train one growth perpendicularly, and one on each side in a horizontal direction a foot from the ground. If the centre growth is strong it may be stopped at 9 inches, when three growths are again selected and trained as the others. We have sometimes had three pairs of horizontal growths in one season by pinching the centre growth. A course of bricks is 8 inches, so that if the growths are trained at every third course they will be 9 inches apart, which is a good distance. This is the best method to fill the wall with bearing wood, and the trees can be pruned by anyone with ordinary judgment. The branches will soon become studded with fruitful spurs, and their production must be encouraged by pinching back closely the young growths in summer. As the trees become old the spurs stand out a great distance from the wall, and the trees sometimes become too crowded with them. It is bad management to allow this. If the spurs are cut back to within an inch of the main stem they will start again and new spurs will be formed. If they are too thick, cut the branch on which the spurs are close back to the main stem. On our Pear wall we have planted at the middle of the space between each tree a single upright cord; these are all well studded with fruit buds from the base to the summit.

Apricots are the next best trees for an amateur to plant, and they must be trained on the fan system. The trees are not subject to insect attacks, but branches die off in a mysterious manner sometimes.

Some of the finer Apples may be grown, and ought to be trained like the Pear trees. The old Golden Pippin is greatly improved by wall culture, and the Newtown Pippin, Ribston, &c., are all worthy of walls.

FRUIT AND FORCING HOUSES.

Vinerias.—The early houses are starting but slowly this season. One reason may be that the sun is not seen for days together, and the temperature by day is not much different from

what it is by night; we fancy that the mild autumn had also something to do with it. The Vines lost their leaves towards the end of summer, and the natural consequence of this is to cause the buds to start, and just in proportion as the buds are started so is it difficult to start the Vines the following season. Of course, it is only the buds towards the extremities of the lateral growths that begin to move in the autumn; the buds at the base do not start, but it is quite certain that they are very considerably weakened by the others beginning to grow at the wrong season.

Many Grape-growers must be in the same plight this season. One grower stated at an exhibition in the first week in July that his Vines had not a leaf on them at that time, and he had just cut splendid fruit from the Vines, to which was awarded a first prize.

If we are to have good Grapes, with perfect bloom, the Vines must not be syringed, and if the fruit is to be kept free from rust it is not safe to apply sulphur to the hot-water pipes. If, therefore, red spider appears what is to be done? The pest unchecked will destroy the leaves, and if this is continued unchecked for a series of years the speedy decline of the Vines must be reckoned upon. We do all that can be done at present by careful attention as to ventilation, moisture in the atmosphere charged with ammonia, &c. to prevent the appearance of spider. If it does appear on the Vines it is destroyed or kept in check by fumes of sulphur from the hot-water pipes.

In a few days all that is left of the late Grapes will be out. The bunches with the laterals attached will be placed in the fruit-room; the end of the branch will be inserted in water. The Vines will be pruned and the houses washed as well as the Vines, as has been already directed in the "Doings." The walls are washed with lime water, to which is added a pound of flowers of sulphur to a pailful of "wash."

Peach House.—Those who have trees in flower in the early house must see that the house is judiciously ventilated, and the flowers must be artificially set. The best way is to pass a small camel-hair brush over the flowers. It is tedious work to go over a large house this way, but two or three of the best blooms on a branch may be done. When the trees have been partially gone over they may be gently shaken, which will disperse the pollen on such flowers as have not been touched with the brush. The trees must not be syringed while in flower, but the paths and borders may be sprinkled every morning. Syringing the trees may be continued as soon as the flowering period is over. 55° is the proper night temperature during the flowering period.

The borders of later houses that are ready to be started should be first well watered and the house kept close for the first week, no more fire heat being required than will keep out the frost. The second week raise the temperature to 40° at night, syringing the trees every morning. Peach trees in pots require but little attention at present. It is necessary to look over them once a-week, watering such as require it.

Strawberry pots on shelves in the orchard house are also watered once a-week, and as soon as the plants show signs of growth they will have an occasional watering with weak liquid manure.

Melon House.—To have ripe Melons about the end of May or early in June the seeds may now be sown in a little bottom heat. Sow in loam with a little leaf mould. The compost should be moderately moist, as it is better not to water the seeds or young seedlings before they are potted-off. The plants will be ready for potting-off as soon as the seed leaves are fully developed. At this season the stalks become drawn up, perhaps 2 inches in length, before the plants are potted. All this stalk must be covered in potting, so that the mould comes up nearly to the seed leaves. The young plants will do better on shelves near the glass than in bottom heat at a considerable distance from the light.

GREENHOUSE AND CONSERVATORY.

Little has been done in this department except to remove decaying leaves and flowers. These are always unsightly, and if allowed to remain they spread disease and decay to the healthy tissues. A few spots of mildew appeared on some of the summer-flowering Heaths and other hardwooded New Holland plants; the diseased portions were at once dusted with flowers of sulphur.

Cyclamens are very much subject to mould on the flower stalks, which causes them to decay. It is best to look over the plants frequently, as decay spreads very rapidly, and much damage is done if there is any neglect.

Roses have been placed in a house to force with a temperature of 55° and a little bottom heat. Roses are easily forced if the plants are kept near the glass and free from insect pests. On the first appearance of green fly the house must be fumigated.

Hyacinths and Tulips in pots never do first-rate if the plants are not kept near the glass when they are in the forcing house. After the plants are placed in the greenhouse it is not material where they are placed.

It has been very unfavourable weather for stage and fancy Pelargoniums. We keep them near the glass and water very

cautiously. The pots must not become dusty dry, else the plants will lose a number of leaves. If too much water is applied the growths become weak. We keep the house as cool as possible, and ventilate freely on every favourable occasion.—J. DOUGLAS.

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

BRISTOL (Spring Show). March 22nd and 23rd. Mr. G. Webley, Holm Wood, Westbury-upon-Trym, Hon. Sec.
ROYAL CALDERDALE HORTICULTURAL SOCIETY. Shows April 5th, July 5th, and September 18th.
WESTMINSTER AQUARIUM. April 15th and 18th, May 10th and 11th, May 30th and 31st, July 5th and 6th, October 4th and 5th.
MAIDSTONE (Roses). June 21st. Mr. Hubert Bensted, Rockstow, Maidstone, Sec.
SPALDING. June 21st. Mr. G. Kingston, Sec.
RICHMOND. June 29th. Mr. A. Chancellor, Hon. Sec.
SOUTHPORT. July 6th, 7th, and 8th. Mr. E. Martin, Sec.
HELENSBURGH (Roses). July 15th and 18th. Mr. J. Mitchell, Sec.
BRIGHOUSE. July 29th. Messrs. C. Jessop & E. Rawnsley, Hon. Secs.
DUNDEE (International). September 7th, 8th, and 9th. Mr. W. R. McKelvie, 26, Enslin Crescent, Sec.

TRADE CATALOGUES RECEIVED.

W. Outbush & Sons, Highgate, London, N.—*Catalogue of Select Vegetable, Flower, and Farm Seeds.*

John Jeffries & Sons, Cirencester.—*Garden Guide and General Seed Catalogue.*

Drummond Brothers, 52, George Street, Edinburgh.—*Catalogue of Vegetable and Flower Seeds, List of Gladioli.*

W. Barron & Sons, Elvaston Nurseries, Borrowash, Derby.—*Descriptive Catalogue of Choice Vegetables, Agricultural, and Flower Seeds.*

William Rumsey, Joynings Nurseries, Waltham Cross, London, N.—*Catalogue of Garden and Farm Seeds, Potatoes, &c.*

James W. Mackey, 40, Westmoreland Street, Dublin.—*Illustrated Amateurs' Guide and Descriptive Seed Catalogue.*

William Rollisson & Sons, Tooting, London.—*General Seed Catalogue, also a List of Subtropical Plants.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (*A. Constant Reader*).—"London's Encyclopedia of Plants" contains woodcuts of stove and greenhouse plants. With its supplement it includes plants of 1855. Price 28 18s. 6d.

TRANSPLANTING HOPS (*F. M. B.*).—The plants for ornamental purposes may be safely moved any time from November to March, not permitting the roots to become dried by exposure.

AUSTRALIAN PLANTS (*J. K. E.*).—You had better consult Dr. Hooker's "Flora of Australia," and Bentham's "Flora Australiensis."

DESTROYING SCALE (*E. W., Dublin*).—The easiest, and we think the most effectual, plan to destroy the scale on your large tree will be to syringe it thoroughly with soft-soap water of a strength of 3 or 4 oss. of soap to each gallon of water, applying it at a temperature of 140° when it reaches the insects. You must calculate that the solution will be considerably cooled in its transit through the air.

GREENHOUSE CONSTRUCTION (*D. E. Conway*).—We do not know where you can obtain instruction. If you inspected one and a frame such as you need they would afford you the best guides.

GERANEA ZEBRINA (*A. Subscriber*).—We should shift the plants which are now 8 inches high into larger pots early in February, and grow-on in brisk moist heat, affording them a position near the glass. The temperature should be 60° to 65° by day from fire heat, and 10° to 15° higher from sun, and at night 55° to 60°. Water moderately. They will, if strong, flower in spring. After flowering the plants should be gradually dried off, affording them a light airy position. Our plants are now in flower in a cool stove, the flowers at this season being very bright and useful. The pots containing the tubers are always placed on a moist bottom, water being withheld when at rest, but the pots are sprinkled overhead daily in sprinkling other plants, and when commencing growth the tubers are fresh potted. They are kept constantly in the stove, starting of their own accord about July, and invariably flower in December and January.

GRASS ON TERRACES (*A. Constant Subscriber*).—Between now and March dress with any rich compost you may have at hand, as the refuse of the garden reduced to mould, or nearly so, adding to and mixing with it or other compost a sixth part of lime, turning over the compost and adding the lime in its unaltered state, which will become slacked in the compost, and before applying the heap should be again turned over. Apply about half an inch thick, and in April remove the rough parts of the compost by raking with an iron rake, and sow over the whole evenly 8 lbs. of *Cynosurus cristatus*, 6 lbs. of *Festuca duriuscula*, 8 lbs. of *Festuca tenuifolia*, 4 lbs. of *Poa nemoralis*, and 4 lbs. of *Trifolium minus*, in mixture for one acre, taking a proportionate part of each kind for the size of your ground, raking lightly after sowing, and rolling well, the surface being in such a state as not to adhere to the roller, and leave for a month, after which mow and roll frequently.

VINE NOT GROWING (*Somerset*).—We cannot account for the Vine not

growing more in a season than 8 inches, other than that it is constitutionally weak, and will never do any good. We should remove it and replace it by the cane to which you allude, cutting it to within 8 feet of the bottom of the wires, leaving that extent of cane for bearing.

EVERLASTING FLOWER (*O. W. D.*).—It is an *Helichrysum*, but which, in the absence of foliage, we are unable to tell. You do not state whether the species is annual or perennial, hardy or tender, so that we are unable to advise you as to its treatment. The other plant we do not know, nor are the leaves any help as they were smashed.

PRUNING ORANGE TREES (*A. D.*).—When the trees are much crowded with wood, having a quantity of worn-out twiggy growth, it is desirable to thin those annually, cutting out the weakest and oldest wood, but avoiding what would be termed a severe pruning, as that would tend to an excess of growth and a deficiency of flowers and fruit. Any irregularities of growth should be cut-in so as to induce compact heads. The pruning should be performed prior to growth or flowering, the early part of February being a good time.

CACTUS NOT FLOWERING (*X. of Sidmouth*).—Repot the plant in March in a compost of three parts turfy loam and one part each of broken bricks of a porous nature, old cow dung, and silver sand, draining well, and place in a house with a temperature of 55° at night (or ainery started in that month will answer well) and 60° by day, with a rise from sun heat to 70° to 80°, watering moderately, and sprinkling overhead twice daily, avoiding a sodden state of the soil, but watering copiously when in free growth. The growth being complete, or in July, place outdoors in front of a south wall, placing the pot on a slate, and water only to keep the shoots or growth from shrivelling. Return to the house by the middle of September, placing in a greenhouse in a light airy position, giving no more water than that required to keep the growths plump, for which very little will be required. After that preparatory treatment your plant will flower.

NAMES OF FRUITS (*L. L.*).—1, Dumelow's Seedling; 2, Brabant Bellefleur; 3, Yorkshire Greeting; 4, Not known; 5, London or Five-crowned Pippin; 6, Fear's Pippin. (*H. H.*).—Flemish Bon Chrétien, a stewing Pear. (*Stuart and Meis*).—Gloria Mundi. (*Consanguit Subscriber*).—They must all be local varieties, for we cannot distinguish any of them. (*Sir W. Bagge*).—Fadley's Pippin.

NAMES OF PLANTS (*P. P.*).—The specimen was smashed. You should send a specimen in flower enclosed in a box.

POULTRY, BEE, AND PIGEON CHRONICLE.

SILKIES.

BY REGINALD S. S. WOODGATE.

PART I.

Of all the different varieties that are now found at our poultry shows, the Silky is certainly one of the quaintest. We notice at exhibitions that very many visitors are struck by these birds, and many are the queries we hear as to the name of this pretty little breed. We find Silkies now are in great request, not, of course, for their laying powers or for table purposes—though the former are by no means inconsiderable—but as sitters and mothers. Undoubtedly no breed supplies such exemplary sitters and nurses as do Silkies. Their great mass of silky-down feathering, their peculiar attention to their chickens, and the long time they run with their broods, make them more especially valuable for rearing early chickens of all breeds, and Bantams and Pheasants at all times. Silkies, too, are great winter layers, and generally in January and February, when broody hens are not procurable, Silkies will be found ready to undertake the business.

It seems the fashion in the present day to breed them small for the exhibition pen; in fact, some think the smaller the better. But much as we admire the tiny specimens, we hope they will not become mere Bantams, for then they would lose half their value as sitters, being only able to cover a very limited number of eggs. On the other hand, the long-legged and coarsely-made birds which are sometimes seen are simply hideous, and have at some time or other been the result of a cross we feel sure. This can generally be recognised by the appearance of single combs, red combs and faces, green or yellow legs, and birds which continually throw four-clawed chickens. We know that some say birds are found in Japan with these disqualifications, and are imported into England, and so trust to the genuine article. This is no proof at all, for surely the birds are capable of being crossed, and are crossed as much in Japan as anywhere else, and that these mongrel specimens certified as being found in Japan and imported into England and elsewhere are the result of some cross there is not much doubt. We have gone thoroughly into the matter, and have waited to write these chapters until we could procure the fullest evidence from Japanese merchants and others who have lived and are living in Japan, and from them we learn that the Japanese Silky pure and proper is just such as we see in the most perfect specimens of the present day. We could quote many cases of birds perfect in every one of our now required scale of points coming from Japan into England within the past eighteen months, and we know on two occasions Mr. O. E. Cresswell has himself come into possession of birds direct from Japan which have won in England in the severest competition. We quite believe that there is a red and single-combed bird with Silky plumage found in some parts of India, but there is no authorised proof, we believe, of these having been imported

into England; and from gentlemen who have seen them there and who knew what they were saying, we learn that they very much differ from the cross-bred and single-combed Silky as found in Great Britain.

Writing, however, on the question of crosses with this breed, we can thoroughly recommend for sitting purposes a cross between a Silky cock or cockerel and Game hens. No doubt a Silky cross with other breeds would make a useful race of sitters, but of the result of the Game cross we can speak with certainty. The chickens from them would be active well-made pullets as large as a Game hen with thick warm plumage. They would cover nine or eleven eggs of the larger breeds, and would be remarkable for their close attention to their eggs and care of their chickens. In these days when broody hens are scarce, it is worth while knowing what will make a good cross for incubating purposes, as Dorkings, Cochins, or Brahmas, pure bred or crossed, are generally too heavy and lumpy to perform this duty well. We recommend this cross to those who want something larger than a Silky generally is; but those who are content with a hen that will cover six or seven large eggs, or only want them to rear Bantams and Pheasants, there is no bird in existence to equal a pure-bred Silky hen for the purpose. We speak from experience, for during the past five years we have used them extensively, and have recommended them to friends, who one and all report the same satisfactory results.

Silksies, too, have other great features for making them popular. So many people in the suburbs of the large towns who like a few fresh eggs, and can only spare a modest portion of their little gardens, do not know what breed to keep. They want some variety which is ornamental and yet useful, but especially which will bear confinement well. Silksies are the birds for them: they do well in a tiny pen, are very hardy, small feeders, and fair layers of moderately-sized eggs, about halfway between a Bantam and a Hamburg. As for hardiness nothing surpasses them. With ordinary feeding and care they do admirably, and though in the last five or six years we have reared close on two hundred of them, we have never had one die from illness. They do not seem to mind wet or cold, and yet ours have had the rudest, roughest sort of protection. The warm silky down seems to protect them and impart much more warmth than ordinary feathering, and hence, of course, their great value for rearing early broods and delicate chickens.

For table purposes they perhaps are objectionable, but then only because of the colour of their skin and bones. Once got over this and they make as delicious eating as any other chickens. We have known them served-up with a thick white sauce, when the contrast is striking between it and the colour of their skin, and they so make a peculiar and ornamental dish. In crossing Silksies, however, breeders must be careful not to have any of the blood into their yards for rearing table birds, as in the second generation the skin will be an ugly and dusky colour, and it is impossible to make such look well on the table whether boiled or roasted. Care must consequently be taken to keep isolated the birds penned for producing table chickens.

The eggs of Silksies are sometimes a pale pink, sometimes a pale buff, and often nearly white. The hens often do not lay more than ten or twelve eggs before desiring to sit, but if not allowed to perform this duty they will generally lay again in a week. Their shells are very brittle, and will break very quickly. We know of no eggs which want so much moisture while the process of incubation is going on, for their shells are liable to become quite dry and brittle, when they will about the nineteenth or twentieth day entirely crack and peel off, leaving the chicken merely in the skin of the shell, which must, of course, be crushed by the other eggs or the feet of the hen. A damp place or a sprinkling of warm water every three or four days will, however, entirely do away with this difficulty.

Silksies are too often liable to elephantiasis or scaly legs. This is generally at first brought on by damp, but if not checked at once it rapidly spreads and grows into large lumps all up the legs, totally destroying the leg-feathering. In this stage it is infectious, and often when once it is rooted among the birds is very difficult to eradicate. At the first symptoms, which can always be discovered by the back of the legs looking as if dusted with flour or some white powder, then it is best to steep the legs in warm water, and then apply compound sulphur ointment, which will generally nip the disease in its infancy. When steeping the legs, however, care must be taken, as the action of the hot water on the delicate leg-feathering will sometimes cause the whole or greater part of it to fall out rapidly, leaving the legs nearly bare.

REIGATE SHOW OF POULTRY, &c.

"Tis an ill wind that blows nobody any good." The Reigate Agricultural Society after having collected their subscriptions, and that, too, from those who subscribed on account of the poultry classes, determined at a late date to strike poultry out of their prize list. As the sequel proved, this was the best thing they could have done for the fanciers of Surrey, because it

left them free to act on their own account without fear of treading on the toes of others, and with a substantial grievance to spur them on in getting up a show for their feathered favourites, in which no bucolic grumblings might be heard of money diverted from beef, and mutton, and pork, and wasted on a "parcel of useless feathers."

The Rev. J. P. Wright of St. Luke's Parsonage, and his plucky fellow-workers, deserve the thanks of all the fanciers of the county for having made the most of their opportunity. Though, as might be expected in a first attempt, there were many things which should, and doubtless will be, altered for the better another year. The arrangements before and during the Show were on the whole most satisfactory. The Exhibition was very good in quantity and quality. Every attention was paid to the wants of the birds; and every facility offered to the visitors, more of whom might have taken advantage of the return tickets issued by the S.E.R. Co. at single fares; the attendance on the first day being rather meagre.

We have before called attention to the want of management at the close of many shows, and the delay in the dispatch of birds from thence. From some shows, though distant many miles from home, our birds always return in good time and together, even when they have to be handed over from one railway company to another in the course of their journey, as is the case unfortunately with most exhibitions to which we send. We wish we could say this of all of them. Swindon was a shocking delinquent. The Show closed on the Friday; our birds reached home more dead than alive from cold and want at 8.30 p.m. on the following Monday evening. On inquiry we discovered that they had been dispatched from Swindon station at 2.20 a.m. on Sunday. A lame excuse was pleaded that the dogs gave so much trouble, &c. We do not intend to exhibit again at these mixed-medley shows, where cats and dogs call off the attention of all concerned. By the way, Mr. Swindon Secretary, we are looking forward with an eager and curious longing to the arrival by post of the illuminated prize card for which you deducted that shilling. We should much prefer the shilling; but we will not grumble if you will send us a good shilling's worth, and ask the post office if they will be so kind as not to stamp it very hard, or the general effect may be spoiled.

At Reigate we have the same cause of complaint. We do not exactly know whether the fault lies with the Committee or with the portly old gentleman who holds the reins of power at Reigate station. It may be six of one and half a dozen of the other. If the reckoning be by the baker's dozen we should credit the half dozen to the latter, whom we can now picture to ourselves pursuing "the even tenor of his way" unruffled by the cackling, and crowing, and cooing of prisoners impatient to reach their homes and liberty.

The Show closed on Thursday, January 6th. We not unreasonably expected that we should find our birds at a station on the same line of railway not twenty miles from Reigate on the evening of Friday the 7th. We were very much out in our reckoning. Hampers kept dropping in while we waited, one or two at a time (most of them should have gone elsewhere); but ours, oh! where were they? One hamper in particular we spotted and pounced on, it was so like ours; but to our chagrin we found that it was mis-sent, and belonged to a brother fancier in a distant county. With the consent of the railway officials we regaled the birds with sopped bread, meanwhile devoutly hoping that the lines of our birds had fallen in equally pleasant places. By the last train one of our hampers arrived. Readers, pity the sorrows of a country parson! We had to face the keen east wind of that Friday night for seven miles on a slippery road, and that one of the most exposed roads in the county, without our most valuable specimens. These we sent for next day; they reached home on Saturday afternoon at about 3.50 p.m. That home is less than twenty miles from Reigate. We ask show committees, Do you think that exhibitors will endure this nuisance long? We have made a resolution never to send a second time to shows from which our birds return irregularly. We are disposed to make every allowance possible; but the unnecessary trouble, annoyance, and expense we have experienced on this score during the past season have almost determined us to give up exhibiting altogether. We ask all true fanciers to join with us in the same resolution, and to adhere to it. Then, perhaps, when entries fall off, committees will of sheer necessity be compelled to understand that they are bound to make arrangements among themselves and with the railways for the speedy dispatch of birds to their homes at the close of their shows. They are very careful about the arrivals, why not equally so about the departure of the specimens entrusted to their care? That great suffering must be caused by the present negligence must be apparent enough. Three days' confinement in a hamper without food or water, as in the Swindon case, is more than the constitution even of a Brahma will stand with impunity; so we find to our cost.—SURREY PARSON.

BOURNEMOUTH SHOW.—There are nine silver cups, and the money prizes good. The show includes poultry, Pigeons, and

cage birds. The classes are well separated, but Bantams require some explanation, for classes 23 and 24 as now worded are the same.

BURSLEM EXHIBITION OF POULTRY, &c.

The third Exhibition was held in the Town Hall and Covered Market on Wednesday and Thursday 12th and 13th inst.

Spanish were a fair lot, as also the Coloured *Dorkings*. The winners in both classes of *Cochins* unusually good; the first in Buffs a grand Golden pair, the Partridge large and well shown. Dark *Brahmas* were very good; and while pencilling was only noticed, the grand points of shape and style were not overlooked. Light *Brahmas* were good, but not equal to the Dark. *Polands* only four entries, but about the best class in the Show, and the extra awarded to the Silvers. *French* a good class, *La Flèche* first, and *Crêves* second and third. *Game* may be passed over as a section which was pretty large, but only the noticed birds at all to our mind; the extra going to a Black-breasted Red cock which combined proportion with style and handling, and not as many of the present-day winners, with legs too long, narrow shoulders, heavy sterns, and large feet. *Hamburghs* were very good as a lot, the contest running very close with the Duke of Sutherland and Mr. Beldon. A splendid pair of Gold-spangles was awarded the special. In the Variety class were Malays, Sultans, *Cochins*, and *Hamburghs*. In *Bantams*, *Game*, the extra was won by a handsome pair of Black Reds. The third in this class contained a grand old cock in *Game* points, but not well matched with a hen. In the next class the first went to Duckwings in the catalogue at the low price of £2 5s., but very readily claimed. The second Piles were a good lot, but somewhat overgrown. In the variety class of Bantams first were a fine pen of Black, as also the third, the second being very good Whites. *Ducks* and *Geese* were such a show as is but rarely seen, scarcely one pen being bad. It would be a breach of faithfulness on our part if we did not notice an occurrence which took place here. In the variety class of Ducks was an alleged new variety. We make no comment.

Pigeons were a very small show, but the Hall a grand place for the purpose, and with so good a list we certainly expected to find a large lot. The quality was, however, good, and the local birds came well to the front in both poultry and Pigeons.

In *Rabbits*, for which small provision was made, were some good ones in Lops; but about one of the best in the Show was a Tortoiseshell Dutch in the Variety class.

SPANISH.—J. J. Powell, Bradford, 2, T. W. Jones, Wellington, 3, S. L. Edwards, Crowthorne. **DORKINGS**.—Coloured.—1 and 2, J. Walker, Rochdale, 3, J. White, Northallerton. Any other variety.—1, W. Rowe, jun., Newark, 2, J. Walker, 3, L. Wren, Leicester. **COCHINS**.—Cinnamon and Buff.—1, J. Walker, 2, H. Tomlinson, Birmingham, 3, W. H. Crabtree, Levenshulme, Manchester. Any other variety.—1, H. Tomlinson, 2, W. H. Crabtree, 3, W. Whitworth, jun., Manchester. **BRAHMAS**.—Dark.—1, Newman and Danby, Wolverhampton, 2, J. Walker, 3, E. Pritchard, Tettenhall, Wolverhampton. Light.—1, M. Leno, Donstable, 2, H. Beldon, Bingley, 3, T. A. Dean, Hereford. **POLANDS**.—1, H. Beldon, 2, A. & W. H. Silvester, Sheffield, 3, G. W. Boothby, Louth. **FRENCH**.—1, E. Walton, Ravenstall, Manchester, 2, W. H. Crabtree, 3, W. Whitworth, jun. **GAME**.—Black-breasted Red.—Cock.—1 and 3, Duke of Sutherland, 2, J. Mason, Worcester. Hen.—1, H. Beldon, 2, A. & W. H. Silvester, 3, T. Cooper, Wakefield. **BANTAMS**.—Brown Red.—Cock.—1, W. & H. Adams, 2, J. R. Pratt, Stoke-on-Trent, 3, H. Beldon. Hen.—1, W. & H. Adams, 2, J. R. Pratt, Stoke-on-Trent, 3, H. Beldon. **BLACK-BREASTED RED**.—Cock.—1, W. & H. Adams, 2, Duke of Sutherland, 3, G. Lunt, Market Drayton. **HAMBURGHS**.—Black.—1, Duke of Sutherland, 2, H. Beldon, 3, Rev. W. Serjeantson, Acton. **BARNET RECTORY**, Shrewsbury. **GOLDEN-SPANGLED**.—1 and 3, H. Beldon, 2, Duke of Sutherland. **SILVER-SPANGLED**.—1, H. Beldon, 2, A. & W. H. Silvester, 3, Duke of Sutherland. **GOLDEN-PENCILLED**.—1, Duke of Sutherland, 2 and 3, H. Beldon. **SILVER-PENCILLED**.—1 and 3, H. Beldon, 2, Duke of Sutherland. **ANT VARIETY**.—1, J. F. Walton, Manchester, 2, H. Beldon, 3, W. & H. Adams. **BANTAMS**.—Game.—Black-breasted Red.—1, E. Walton, 2, E. W. Ardagh, Worcester, 3, E. Bell, Burton-on-Trent. Any other variety.—1, J. Goulding, Bowden, 2, R. Brownlie, Townsend, 3, E. Walton. **BLACK OR WHITE**.—Clean legged.—1, J. Walker, 2, H. Beldon, 3, W. H. Shackleton, Bradford. Any other variety.—1 and 2, J. W. Lloyd, Kingston, 3, M. Leno. **SELLING CLASS**.—1, J. Walker, 2, J. Dykes, Stapley, 3, F. Jagger, Baildon, 4, S. Ford.

DUCKS.—Rouen.—1 and 3, J. Walker, 2, Duke of Sutherland. **WHITE AYLESBURY**.—1 and 3, J. Walker, 2, J. Hedges, Aylesbury. Any other variety.—1, A. & W. H. Silvester, 2, J. Walker, 3, M. Leno. **SELLING CLASS**.—Drake.—1 and 3, J. Walker, 2, Duke of Sutherland. **PAIR**.—1, Duke of Sutherland, 2, J. Walker, 3, J. Hedges. **GESE**.—1 and 2, J. Walker, 3, W. E. Burrows, Derby.

TURKEYS.—1, W. Wykes, Bingley, 2 and 3, J. Walker.

LOCAL CLASSES.—*Spanish*, *Dorkings*, *Cochins*, *Brahmas*, *French*, and *Game*.—1, S. Hemmings, 2, C. Heath, 3, F. Cooper. *Hamburghs*.—1, J. Turner, 2, Mrs. Flynn, 3, T. Boulton. *Bantams*.—1, T. Fowkes, 2, A. Heath, 3, W. Blakeman. **PIGEONS**.—*Carriers*, *Black*, *Cock or Hen*.—1, T. M. Usher, Wakefield, 2, J. Walker. Any other colour, *Cock or Hen*.—1 and 3, J. Walker. *Pouters*.—1, H. Pratt, Hampton-in-Arden, 2, H. Yardley, Birmingham, 3, J. A. Bours, 4, Rev. W. Serjeantson. *Runts*.—1 and 2, H. Yardley. *Tumbler*.—1, W. & H. Adams, 2, H. Yardley. Any other variety.—1, H. Yardley, 2, W. & H. Adams. *Long-faced*, *Balds*, or *Beards*.—1, R. H. Unsworth, Stockport, 2, J. Brown, Manchester. *Jacobins*.—1, J. Thompson, Bingley, 2, H. Yardley. *Barbs*.—1 and 2, H. Yardley. *Dragoons*, *Blue*.—1, R. Woods, Mansfield, 2, G. S. Prentis, Cirencester. Any other variety.—1, R. Woods, 2, G. S. Prentis. *Anticorns*.—1, J. J. Bradley, Birmingham, 2, H. Yardley. *English Gulls*.—1, T. M. Usher, 2, R. H. Unsworth. Any variety.—1, H. Yardley, 2, J. F. Phelps, Ross. *Selling Class*.—1, J. Walker, Smallthorpe, 2, C. Norman.

LOCAL CLASSES.—*Carriers*.—1, J. Walker, 2, R. Hart, Dragoons.—1, E. J. Rowley, 2, J. Walker, 3, E. J. Rowley, J. Walker. *Fighters*.—1, H. W. Nixon, 2, J. Norris. Any variety.—1, A. J. Ridgway, 2, W. Tomkinson.

CAGE BIRDS.—*Belgians*, *Clear or Ticked*.—1 and 3, H. Davies, Wolverhampton, 2, S. Bunting, Derby. *Norwich*, *Clear Yellow*.—1, 2, and 3, J. A. Bours, Coventry. *Clear Buff*.—1, J. Adams, Coventry, 2 and 3, J. A. Bours. *Partridge*.—1, J. Adams, 2 and 3, J. A. Bours. *Crested*.—1 and 3, J. Yallop, Newark, 2, G. E. Russell, Brerley Hill. *Lizards*, *Golden-spangled*.—1, C. Clemenson and Ellerton, Darlington, 2, S. Bunting, 3, J. A. Bours. *Silver-spangled*.—1, P. Duckworth, Macclesfield, 2, J. Stevens, Middlesbrough, 3, S. Bunting. *Broken Cap, &c.*.—1 and 3, S. Bunting, 2, W. & H. Shackleton, Rochdale. *Coppys*, *Yellow or Buff*.—1, J. Yallop, 2, W. & H. Shackleton, 3, C. Johnson,

Macclesfield. *Plain Heads*.—1, J. Yallop, 2, W. & H. Shackleton, 3, C. Johnson. Any other variety.—1, 2, and 3, J. Adams. *Males*, *Goldfaced*, *Yellow or Buff*.—1 and 3, S. Bunting, 2, J. ST. AUSTELL POULTRY SHOW.

EVERY year we find this little Exhibition in a more thriving state. Really the quality of the birds, the management, and general arrangements are very good indeed. We believe at the bottom of their success may be traced the fact that so many of their Committee are genuine fanciers themselves. The Rev. G. F. Hodson awarded the prizes, and in most cases gave great satisfaction. The catalogues with awards were posted by an early post, and we believe every prizewinner had sent them gratis the day after the Exhibition an illuminated prize card.

Dorkings came first on the list, and to the Coloured went the cup for the first section, and perhaps quite deservedly, for the cock is a good bird and of grand colour. Second and third were fair pens. The other Dorking class only mustered five entries where Silver-Grays were first, and Whites second and third, the latter rather small and too much like *Hamburghs*. *Cochins* had two classes; in the one Buffs and Whites competing, in the other Partridges had it all to themselves, the poor Blacks having to take refuge under the covering of the variety class. In the first class Whites won first, and we have not seen such a bird as the cock in this pen was for a long time. He is quite faultless but for his comb being a little rough. The hen with him was also very good. Second went to nice Buffs of pretty colour, and third again to Whites, where the cock was a good bird. In Partridges the winners were all good and well selected; the first and second being well ahead. *Brahmas* were better in numbers than in quality. Among them there were not many worthy of notice save the winners. The hen in the first-prize pen of Lights was good and well shown. Mrs. Holmes also sent a nice pen, which were highly commended. *French* made a fair muster; *Crêves* came in second between two pens of *Houdans*, the first of which were decidedly good and neatly marked. *Game* were very good; they always are here, for some good fanciers live in the neighbourhood. They had three classes and a cup, which fell to the Brown Reds. Both these classes were fine, but we fancied all the birds were rather out of bloom; perhaps the late weather has had some effect upon them. In the other *Game* class all the prizes went to Duckwings, a fair lot of birds; 121 (Feast) middling Piles. *Spanish* made nine pens; all the prizes went to Bristol. The birds were mostly chickens and well shown, the pullet in the first-prize pen being remarkably good, and with a good-faced cockerel. *Polands* only made five pens, but the quality was admirable. White-crested Blacks again scored another triumph against the Silvers. The winning pair were beautiful; 133 (Lecher) another good pair of the same colour, but younger. Both the Silvers were, however, good; the second cock especially heavy in crest. *Hamburghs* were a very fair collection. The cup went to Silver-spangles. We thought the winners were well chosen. After them Gold-pencils were the best, the Silvers only making up four pens, where the winners were fair birds. *Malays* and *Indian Game* were classed together; Malays, however, won all the prizes, and a good lot of birds they were. The breed is another of those which have made great progress of late, and now wants help from the exhibitors to push the breed yet more. Some so-called Indian Game came in for high commendations, but we heard others say there was not a bird in the class with pure Indian blood in its body. The Variety class was very pretty, and some good Silks won first, Black *Hamburghs* taking the other two prizes. *Game Bantams* were only middling, all the birds seeming to be coarse and large. The next class was very beautiful and remarkable for many pens of admirably Laced birds; a neat pair of Blacks came in, however, between them. *Minorcas* made fifteen pens, of which the majority were again Black. They seem to be another breed which is quite shaking itself down into an established place. We liked all the winners, and thought other prizes could well have been given had there been any more to allot. In single cocks a White *Cochin* was first, a nice Brown Red *Game* cockerel second, and a Dark *Brahma* third. The Sale classes were large, and many very fair birds were to be picked up. *Rouen Ducks* were a nice lot, and so were the *Aylesburies*. *Geese* and *Turkeys* only made five pens together. The winners were, however, good, and were worthy of their prizes, though they won them so easily.

In *Pigeons* *Carriers* made a good class. In *Pouters* a good

wherever honey can be gathered, let those who want large harvests of it keep hives of great powers and capacities.—A. PATTINGRAW.

EXTRACTED HONEY VERSUS COMB HONEY.

RESUMING the subject of my last communication on this point, I may take it for granted that all bee-keepers are agreed as to the superiority of honey in the comb to that which is extracted from the comb by whatever process, and that our efforts should be mainly confined to the production of the largest quantity of the purest honeycomb in saleable form.

A letter forwarded to me from your office, approving of my remarks on this subject, asks for information as to the shape and size of boxes. At this moment my eye is resting on a description with figures of the "American International Hive," as patented and sold by H. A. King & Co., New York. It contains thirty-two honey boxes, some of which are arranged over the hive, and the rest are piled up at each side, having communication by means of holes with the hive itself. Rejecting twenty-four of these small boxes—those I mean which are adapted to the sides—there remain eight resting on the top board. Each of these eight boxes is large enough to contain two thick combs 5 inches high and 6 inches long. I further observe that each box is constructed as a frame, having glass in front and at the sides. Nothing can be imagined neater or more handy and attractive. When filled with honeycomb these boxes would command purchasers anywhere, and create a market at once wherever offered for sale. Methinks, however, they are too small for our needs in this country. In my former paper I recommended four boxes instead, which, of course, would hold double the quantity of honey; but a size between would perhaps be most suitable. This would give room for six such boxes of very convenient size. The communication between these boxes and the hive below should be by narrow passages, just wide enough to allow free movement to the worker bees, and to them alone. In bar-and-frame hives they can be made exactly to correspond with the spaces between the combs below, which, of course, is a matter of importance.

I am trying to obtain a sample hive from New York complete for trial next summer; but any person with ordinary mechanical powers and a few tools could construct his own boxes, or have them constructed by any carpenter, quite sufficiently perfect for his purpose. I am well aware there is nothing new in this management, but it seems to me that for many years our great bee-keepers have been going on a different track, following the craving of the public at honey shows for something striking and grand. It now appears by general complaint that the huge supers which it has been the fashion to procure, never mind at what cost of honesty and straightforward dealing, are not paying. So after all "honesty is the best policy." It cannot be amiss, therefore, to lead our friends back into better ways among the good old paths, and certain I am that none will regret adopting a system of honey-getting which in the long run will be found to be the most profitable.

It is curious that Mr. Hunter and I should have read so differently the voices from America on the subject of the "extractor" and run honey; but no doubt there are different voices, and he and I are both right in our different views of the matter. It may be that in some parts of the great western land run honey and the extractor are popular. There is something charming to the ear, if not to the sight, to hear of 1541 lbs. being taken from five boxes, and again of "500 lbs. of comb honey and 185 gallons extracted from forty-four stocks," &c. But from other parts of the country come voices telling equally of quantity but lamenting the quality, and crying especially over the glut in the market which has supervened. I say, Let us go in for quantity if you like, but let us look mainly to the quality of our honey, for quantity, if of inferior food, soon palls on the appetite and damages the market; but honeycomb of excellent quality is like those more delicate sweetmeats whose enjoyment only creates a healthier appetite for them, and consequently increases their sale year by year. *Sat verbum sapienti.*—B. & W.

OUR LETTER BOX.

SAWDUST FOR FOWLS (T. W. E.).—The objection to sawdust is that it is an indigestible substance, that it fills up the space that should be occupied by nourishing food, and that it is not capable of being ground in the gizzard. Another objection is that it remains unchanged, causing great discomfort, and inducing excessive drinking. There is little to condemn in its use if it is only for the purpose of cleanliness in a house, but it is very injurious where the food is thrown down on it and the birds pick it up with their food. This is especially the case at exhibitions. It is only where it is unavoidable that the fowls swallow it. Instinct is strong in them, and forbids them to pick up anything so injurious. It is as good for human beings as for fowls.

CANARY HEN PICKING HERSELF (M. S.).—Your Canary, although apparently healthy, may be uneasy and suffering from a heated state of the blood through being kept in a warm room, or she may, perchance, be troubled with parasites, which to an unpractised eye would not be noticeable. The parasites are of the bag species, diminutive in size, but vary in colour according to age. This kind of vermin accumulates very fast during the Canary breeding season, and are troublesome customers to get rid of. The annoying nature of the red

mites, as they are called, cause birds to peck themselves much, especially during night-time, when the bugs leave their haunts to feed upon the life blood of the birds. In day-time the vermin mostly keep to their haunts—the crevices of the cage—and it is there they may be found. In the first place wash the bird well with soap and lukewarm water, using a partly worn-out shaving brush for the purpose, or a piece of old flannel. Don't be afraid of applying soap pretty freely to purify its feathers during washing. Rinse afterwards in clean warm water. Extract or dab out as much of the moisture as you can from the feathers with a muslin or cambric cloth, and then let the bird gradually dry in a cage before the fire. When sufficiently dry remove it to another cage, and scald and cleanse that you have removed the bird from. If after the operation of washing you find the bird continues to peck itself, dose it with a drop of castor oil, after which let it have betwixt the wires of the cage a piece of salt (no sugar, please), which will act as a blood-purifier. Supply a bath daily; and as early in approaching spring as you perceive the dandelion root shooting forth its head in sheltered situations let your bird have some to eat. The mixture of the four kinds of seeds you name will be best for the bird; only in the place of the rape, which probably you may not have scalded, and which may be of the large black kind, substitute it for that known as summer rape, or otherwise in its place supply small hempseed. The large black rape seed is very drastic and heating, and is very injurious to young birds unless scalded. Keep a rusty nail in the bird's fountain.

BEE JOURNAL (J. T.).—There is not one published.

HONEY WINE (A Straw Hive).—This is usually called mead, it may be thus made:—"To a gallon of water put 2 lbs. of honey and 1 lb. of sugar; boil for an hour, put in the whites of four eggs to clarify, and skim it quite clear whilst boiling; then put it into a clean tub, and let it stand for a week, putting in a toast with honey to make it work; then turn it, put in the peels of three or four lemons, let it stand for a month, and then if it is not sufficiently fine put in more honey, and let it stand longer." We do not know the machine you mention.

VEGETABLE MARROW PRESERVE (D. D.).—The common oval yellow-fruited is as good as any for the purpose. The seeds and rind being removed, boil the flesh with very little water, adding lemon peel to give a flavour, and sugar according to the sweetness desired.

REMARKS.

- 13th.—Frosty, with an unusually white fog (for London); dull afternoon snow at 6 P.M.; a cloudy night.
14th.—Snow everywhere below, and dense heavy clouds above; bright by noon; fine afternoon; very cloudy at night.
15th.—Snow on ground, and leaden-coloured clouds above; very dull all day; thawing a little.
16th.—Very dull all day but no fall; colder towards night.
17th.—Fair, but very cold and dull, soon clearing off; a bright frosty day, the finest we have had for some weeks.
18th.—A very thick fog in morning, but soon clearer, followed by a damp disagreeable day; thawing fast at night.
19th.—Snow all gone during the night; rather dull and dark at 9 A.M., sun shining brightly before 11.30; remainder of the day beautifully bright, almost spring-like, and the stars very bright at night.—G. J. STIMON.

COVENT GARDEN MARKET.—JANUARY 19.

THE market is amply supplied with all kinds of goods, and prices are generally below the average, business still keeping inactive.

NOTES ABOUT POTATOES.

DUNBAR REGENT, with Walker's Early Regent, Walker's Improved Regent, Paterson's Regent, Prince Regent, and nobody knows how many other *aliases* the York Regent—the old true variety—is found under; it is one of the most useful of Potatoes, combining heavy cropping, hardness of plant, size without coarseness of tuber, good cooking qualities, with full flavour, and it is a good keeper. It is a staple kind—unsurpassed for bulk combined with quality, and is justly popular for field or market purposes.

Other qualifications than bulk and fair quality are expected to be found in a garden Potato. Size is of some moment, but it must not approach to coarseness; the tubers should be uniform, with few that are small and unuseable. Appearance is all-potent; a Potato suitable for a gentleman's table must be very regular in outline, have a good clear skin, and the eyes few and even with the surface. Then it must not be "sad," but dry and mealy, free from fibre, core, or discoloration of flesh, and should possess a flavour so extremely delicate as not to be distasteful to refined palates. In growth it must be dwarf, having stiff short haulm, and the produce must ripen early. Of that type are Mr. Fenn's productions—models of what Potatoes should be for garden cultivation.

Of late years many people have been smitten with the disease of "Potato craze." Wonderful things were to have been accomplished by Mr. Paterson's seedlings, but only one of note is left—Victoria, unless, indeed, we admit the claims of Bovinia, the biggest and ugliest, and at the same time most worthless of Potatoes. Then there has been an invasion of American Potatoes, those introductions with which we have been favoured with of late years.

The object of all enterprise in Potatoes would appear to be to increase size and quality, and justly so, for to add size without corresponding goodness is to take a step backward, which will require at least two steps to bring in advance of the starting point. Now, we have in the American kinds a bulk which cannot fail to satisfy the most hopeful aspirant; but Potatoes to take with consumers must have useful cooking qualities—mealiness and good flavour. Which of the American varieties possess these qualities? The earliest? None that I have tried (and to those these remarks must be held to apply) possess them in a degree approaching our older sorts. Early Rose is certainly a prodigious cropper, but even in light soils with high culture it is waxy, and is neither pleasant to look at nor tempting to eat. Extra Early Vermont is very much superior to Early Rose, finer in form and regularity of outline, and superior in cooking quality to it, resembling our kidney-shaped earliest more than any other American kind, also in good cooking properties, and is besides very productive, but exhibiting no improvement over Myatt's Prolific or Veitch's Ashleaf, but rather

inferiority, and it is needlessly extending names to retain it.

Of second earliest Brownell's Beauty (Vermont Beauty) is a very heavy cropper, with strong short haulm, and for so large a tuber is fine-looking, the eyes not being so deep as in the old "Cups" or Red-skinned Flourball. In quality second-rate will accurately satisfy its claims, though as a baking Potato I am informed (for I cannot appreciate a "roasted tater") that it is first-rate. Snowflake is a great advance in appearance, being very handsome and noble-looking, the eyes very little depressed, with a clear white skin, great regularity in the tubers, large and even-sized, and in flavour and good cooking properties running very close for equality our Dons, Rocks, and Regents, "Dunbar Regent" not excepted, whilst for cropping it is the equal of any of those. Its size is too large for a gentleman's table, but for market purposes it will no doubt put forth the claims, which are justified by its merits.

Late American kinds I have represented by Late Rose, which is large, even in form, and shallow-eyed, a very heavy cropper, and of good quality. It is a kidney, and too long to have a good appearance at table. Excelsior is a handsome flattish-round sort, not remarkable for cropping, but possesses good cooking qualities. Willard as I have it is a round-flattish kind, of a very even useable size, deep pink in colour of skin, and russeted, very white in flesh, cooking well late in the season.

Not one of those mentioned surpass our Roughs, Blues (Skerry), Flukes, Fortyfolds, White Dons, White Rocks, or Regents in those essentials of productiveness and quality which meet acceptance with growers and consumers. Of field or winter kinds I have a number which I must, curiosity being satisfied, discard for want of room, experience having shown to demonstration that large autumn and winter kinds in the highly-manured soils of gardens attain to a size and coarseness prejudicial to their appearance and use as compared with the same sorts grown under the best stimulating culture of the farm, to which they will be relegated. Snowflake, however, does not exhibit the coarseness of other kinds, and will therefore be retained. I will now proceed to an account of Rector of Woodstock, Early Market, and Bountiful.

Rector of Woodstock is a second early, flattish round in form, with a white slightly russeted skin; tubers of medium size, as even in size as they are regular in form, boiling excellently, very floury and very delicate in flavour; it is a good cropper, ripening-off early, and is not liable to disease. But this, like most of the second earliests, if planted late succumbs to disease. It has a dwarf and very compact haulm.

Bountiful is a second early red kidney, is a very finely-formed tuber, almost without eyes, very round for a kidney, rather long and pointed, and is extremely beautiful, and possesses when cooked great dryness, with a peculiarly delicate nutty flavour. The haulm is short, and produces a heavy crop of even-sized tubers.

Early Market, a first early, flattish-round in form; eyes slightly depressed; skin yellowish, slightly russeted,

having a very handsome appearance. It is very mealy when cooked, and of the finest flavour. The tubers attain to a good size, exhibiting remarkable evenness, and are freely produced. The haulm is very short, shorter than any other, and very dissimilar to any I know.

So thoroughly satisfied am I with the sterling merit of those three kinds, that I shall add with every confidence Early White Kidney, certain that it will prove a fitting companion for Early Market in first earlies. Not the least advantage these kinds possess over older sorts is their refusal in highly manured soil to grow into coarseness. Considering their extremely fine appearance, high quality, and fertility, they are likely to have a long run of popularity for garden culture; whilst for field cultivation against kinds of their own season I feel certain they would compare favourably, but to compare them with Regents is the equal of comparing a mountain sheep with a Leicester. There is room enough for Early Market, Bountiful, and Rector of Woodstock from June to November, at which season Dunbar Regent is at least a waxy lump.

Turning from the newer to older sorts, Myatt's Prolific Ashleaf and Veitch's Ashleaf are the best of the forms of this type, being good alike for frame or forcing purposes as for garden culture; whilst as a second early I am run out, designated, of every sort but the Lapstone, to follow which there is no better than Victoria, sometimes called "The Queen." As well may "Dunbar Regent" be called "The King."

I must crave a few words on disease. The fungus came upon us very early last year in the form of the "curl." The curl caused considerable alarm in Scotland and the northern counties at the latter part of the last century. For this grand curl discovery, advancing us no nearer a remedy for the disease than did the offering and withholding by the Royal Agricultural Society of Earl Cathcart's £100 prize, a gold medal was justly given by the Royal Horticultural Society. What a reward science obtains as compared with practice! (Let us hear no more of the non-recognition of science.) Practice was represented by Mr. Thomas Dickson of Edinburgh so far back as 1806, who was not only cognisant of the new disease, but ready with a remedy—viz., employing as seed-stock unripe tubers, and which, it is curious to note, was one of the best means for the prevention of that disease so disastrous to the Potato crop of 1845 and subsequently. Science in this instance verifies but does not advance practice; and as the resting spore is found to exist in the tuber tissue, it is vain to hope for any remedy other than preventing the spore from obtaining a hold of the tuber and manifesting itself in "curl." This is secured by taking-up the seed-stock when full sized but with the skin barely set. The ripening process, which gives the tubers their esteemed farinaceous quality, just commencing is thereby stayed, and we obtain produce through which the mycelial threads of the fungus have not run, whilst the tubers are for every purpose of growth better than ripened sets, giving the most healthy and productive plants.

Practice has also shown that seed had from a colder or more northerly climate gives a stronger sturdier growth of plant, increased yield, and higher quality than is obtained from seed had from a warmer climate. Those who have had seed Potatoes from Scotland for growth in the warmer parts of England will have had gratifying proof of this. Change of soil also exerts considerable influence on vegetable growth, and in none more than the Potato, and it is from these attentions to the result of practice that we may expect freedom from disease in Potatoes, of which I had none free the last season in earlies or second earlies, except Bountiful, nor can I say the crop has been good or of high quality.—YORK REGENT.

LILIUM AURATUM SOWING.

Mr. McIntosh of Dunevan, Ostlands Park, has ripened in his garden some seeds of those noble plants of the *Lilium auratum*, of which we published a drawing in our No. 757. Seedlings may be easily raised; and knowing that Mr. Douglas at Loxford Hall had so propagated this Lily we asked him for some relative information. He replies as follows:—

"I had an exceedingly fine variety of *L. auratum*, which appeared amongst a lot of bulbs that had been received direct from Japan; and wishing to increase the stock of it more quickly than by the usual offsets from the old bulbs, one of the best flowers was selected and the stigma dusted with pollen from the anthers of the same flower. In due time a fine pod of seed was obtained, which ripened about the end of September. The seeds were shaken out and kept in a dry place until

April; they were then sown in 6 or 7-inch pots, and the best compost is one of turfy loam and peat with a little leaf mould. The pots were filled up to within an inch of the top, and the mould was made quite level; on this the seeds were sown, covering over with a quarter of an inch of fine mould. The pots were then placed in a hotbed with a gentle bottom heat, along with some pots of *Gladiolus* seeds. In two weeks the *Gladioluses* were quite up or fast appearing aboveground, but no signs of the young Lilies. Week after week passed and the *Gladioluses* made rapid progress, but still no young Lilies. The pots were examined, and the seeds were quite fresh. We kept the soil moist, and the pots were moved about in cold frames all the season until the following April—twelve months from sowing the seeds. They were still fresh, and when the pots were again placed in heat the young plants appeared. They made nice little bulbs the same season, and have been now potted off. With liberal treatment they will flower in three or four years."

NOTES FROM MY GARDEN IN 1875.

VEGETABLES.

If I could look with some little degree of satisfaction on my little greenhouse during the past season it was very different in the vegetable department of the garden. It was not merely the plague of weeds which daily annoyed me, and for which I could find no remedy, but that the peculiar character of the season interfered with the quality and quantity of the crops. Peas, for example, what a plague they were! and yet I went in for a good many sorts, hoping to gain some experience of their value; but the early sorts were completely spoiled by the drying winds of April, May, and the early part of June, while the wet of July sent the later varieties growing at such a rate that "Jack and the Peastalk" might have been substituted for the old familiar Beanstalk, and as a consequence the crop was considerably diminished. The sticks were not tall enough for the Peas, which hung about in most admired disorder. Of those which I had the following notes were what I was enabled to make.

Emerald Gem.—This has fully borne out its previous good character; nor can I at all understand why it should be considered the same as Danecroft Rival, for if there were no other distinction its very robust growth would surely distinguish it from that variety which was always described as delicate in flavour and is excellent.

Bijou (Suttons).—An early dwarf Pea of the Little Gem type; and as that variety has considerably run out it will be of great value in replacing it. Besides, the pods are larger and better filled.

First Crop Blue.—A second early, distinct, blue wrinkled Pea. Flavour good.

Best of All (Maclean).—I am further confirmed by this season's experience that there is no Pea for a general crop superior, if equal, to this for an amateur. Its length is about what we want—3 feet, so that we do not require very tall stakes. How far it will bear comparison with Mr. Turner's new Pea Dr. Maclean I do not know; but all that I have seen of the latter, and all one hears, makes it clear that it is a Pea of first-rate excellence.

Giant Emerald Marrow (Suttons).—This is without doubt a grand Pea; and although, as I have said, the wet season at the time it comes in—end of June and beginning of July, prevented one's forming a thorough estimate of it, yet its qualities are undoubted. It is very prolific; the pods fill well, containing from eight to ten peas, which boil a beautiful green colour and are of excellent flavour, a quality in which some of the new varieties are considerably wanting.

G. F. Wilson.—A very fine Pea of the Veitch's Perfection type, and, like it, possessing the qualities of productiveness and good flavour.

Duchess of Edinburgh (Suttons).—A very handsome, prolific, and good-flavoured Pea. Its height ought to be about 5 feet, but this year it ran up to 6 and 7; and in a dry season I believe it will be very valuable.

Besides these I had four small packets sent me by my friend Mr. Laxton of his new Peas. From so small a quantity one can hardly judge the value of a new Pea; but of the four, Unique and Dr. Hogg, the former a dwarf Pea and the latter a green wrinkled one, seemed to be very promising.

From Peas one naturally turns to Potatoes; and bad as the season was, I consider myself to have been exceedingly fortunate. The early sorts in my garden turned out very well.

I planted *Lee's Early Hammersmith*. It again proved to be a valuable kind, most probably a selected strain of the Ashleaf, but more robust, and the flavour equally good.

Rector of Woodstock (Fenn).—Unfortunately this promising variety with me was very much attacked by the disease—more so than any kind I grew this year. I have found it so for two years, and hope on a third trial I may be more fortunate. I am the more surprised at this, as Mr. Fenn, I see, says it has been very free from disease, and yet my soil is not heavy.

Snowflake.—Without doubt, as far as my judgment goes, the only one of the Yankees worth growing. It again did very well with me, and we all pronounced its flavour to be good, while in colour it well deserves its name. Some have a fear of its degenerating: for two seasons I have found it good.

The following kinds were grown in a field of sandy soil—

Lapstone.—I can in no way alter my opinion of this Potato—that for flavour there is none to equal it. It wants more robustness, as it is liable to disease.

Hundredfold Fluke.—I have found this, as before, but little affected with disease; and although not to my own taste quite as to quality, it is much liked by some of us.

Red-skin Flourball.—This again has proved, notwithstanding the season, a very excellent kind for the purpose for which I use it—baking, and it certainly resists the attacks of disease better than most kinds.

Victoria.—I can say nothing better of this than what is written to me by one of our most eminent seedsmen—"The Victorias you send are splendid; we have nothing like them about here."

I also received from the Messrs. Sutton of Reading a sample of their new kidney Potato *Magnum Bonum*. It boiled well and was of good flavour, but I hope to be able to judge of it this year by growing it under my own eye.

I have this year again followed out my plan, as far as the season would permit me, both of planting and taking up early; and although not able to perform either operation quite as soon as usual, I have found the advantage of it; and although some of the Potatoes did not seem to be quite ripe when taken up, I have lost very few since. Out of five sacks of Victorias I do not think there is a peck of diseased tubers.

I wish I could write differently than I do of Tomatoes, but I fear I must give up all hopes of growing them. For now three seasons I have tried it, and each year the failure is more complete. They grow well, come into fruit and swell, but they become attacked with a disease very analogous apparently to that of the Potato, and not one comes to perfection. I tried both *Conqueror* and *Excelsior*, and the result was the same with both. That it is to be referred to atmospheric causes is quite clear, for I potted a few of the plants from the same seed-pan and placed them in the greenhouse, and these were quite free from any disease. Many persons in this neighbourhood have complained of the same, and I very much fear the result must be the abandonment of Tomato-growing here.

Cucumbers I have but small facilities for growing, having but one frame, and so must confine myself to one sort. It is a matter, therefore, of some consequence to me that I have a good one. This year I tried *Duke of Connaught*, and found it to be a very valuable kind, producing fruit freely, sufficiently long for any purpose, and of good flavour. It is a white-spined variety, and has a remarkably small handle, so that nearly all the fruit is fit to use.

French Beans.—*Canadian Wonder* still maintains its character, and I do not care to grow any other variety but it. It is good at all times, and is a great favourite with greengrocers on account of its fine handsome appearance. It is also of remarkably good flavour, and the amount it produces simply prodigious.

In other vegetables I have nothing particularly worthy to record. Some of the old standard kinds are still unsurpassed, but occasionally novelties do force themselves to the front, and therefore it is well that their merits should be recorded; and the experience of many will be most useful, even although like myself their "diggings" are but small.—D., Deal.

WITLOOF.

A new and very excellent vegetable was shown for the first time in this country at the meeting of the Fruit and Vegetable Committee of the Royal Horticultural Society on the 19th inst. It was raised from seed supplied to the Society by Messrs. James Carter & Co., and was grown in the garden of the Society at Chiswick.

Witloof or Witteloof is Flemish, and signifies White-leaf, from the plant being blanched in the same way as *Seakale* and other vegetables. It is very common in Belgium and especially about Brussels, where it is sometimes called *Chicorée de Bruxelles*. It is blanched and used in the same way as *Seakale*, and the smaller side shoots which are produced after the crown is cut form an excellent salad. We have for many years remarked this excellent vegetable at the tables of our Belgian friends during the winter and spring months, and have been surprised that through the enterprise of our generally enterprising seedsmen it has not sooner been introduced into this country. We have grown it for several years from seed procured in Brussels, and found it to succeed perfectly; and now that it has been introduced by Messrs. Carter & Co., to whom we are indebted for the accompanying illustration, we

Fig. 18.—Witloof.

shall expect to see it become as widely distributed throughout the country and in our markets as forced *Seakale* or forced *Rhubarb* are.

Witloof is a variety of the common *Chicory* (*Cichorium Intybus*) which has been long cultivated in this country for salads, but is totally different from that variety inasmuch as the latter, to be well adapted for salads, requires to have a small midrib and a thin blade to the leaf, whereas in this "*Chicorée à grosse racine améliorée*" the great object is to have a thick and fleshy midrib and blade so as to have it as succulent as possible.

Our mode of culture has been to sow the seed on good well-manured soil in drills 9 inches apart in the open ground in the end of May or beginning of June just as the weather per-

mits, and when the plants are strong enough to thin them out to 6 or 8 inches apart. The roots are taken up in the end of October and November, and all the leaves removed so as not to injure the crown; these are then placed in circumstances which are most convenient for blanching. The different ways of doing this will be suggested to people by the conveniences they have at their disposal. Those who have a Mushroom house may use that; those who have not can plant the roots in boxes and put them under the stage of a greenhouse, protecting them from the light. The mode we adopt is the following, which we have seen in Belgium, and which will be the most convenient for most households.

In the corner of a cellar, a stable, cow-house or shed protected from frost, form a cone of horse dung 2 feet in diameter at the base and as high as may be desired. Outside of this place a layer of soil on the floor 18 inches wide and 4 or 6 inches thick. On this place the Chicory in a row close together, with the roots towards the horse dung and the crowns just outside the edge of the soil. Upon these put a second layer of soil and then another layer of roots, proceeding in this way till the top of the cone is reached. If the apartment is dark it will not be needful to place any covering over it, but if any light is present it must be covered with a mat or any other covering, and this again enveloped in straw, long dung, or any other litter. In this case sticks will require to be stuck into the cone at various distances, and protruding about 9 inches to prevent the covering from pressing against the Witloof when it begins to grow. The fermenting mass of dung stimulates the roots into growth. A more homely way is to select a dry piece of ground, and dig out a trench as for Celery, in which plant the roots in a row close together. Let this be covered over with hoops or branches of trees, and then enveloped in a thick coat of long dung. Seakale pots may also be used as for Seakale.

When the crowns have grown 4 to 6 inches in length they are to be cut off in the same way as those of Seakale and so as not to disturb the roots in the cone, which are to remain and to be kept covered up, when they will produce an abundant crop of small shoots, furnishing a constant supply of excellent salad all through the spring months. The crowns are to be stewed in gravy or in any other way that the taste of the household may desire, and served in the same way as Seakale.

We can strongly recommend this to every person who has a garden, and we would do so especially to enterprising forcing gardeners, who may reap as rich a reward from its cultivation as Mr. Myatt did by the introduction of Rhubarb.

TREES ON WHICH MISTLETOE GROWS.

OBSERVING in your issue of the 13th inst. an article on the Mistletoe question, I thought it may not be unacceptable to your readers if I name a few trees on which it may be seen growing with us—namely, the common Lime, Whitethorn, common Maple, Black Poplar, Willow, wild Crab, and a variety of Sycamore seen growing rather extensively in Canada (one example of which we have here in the pleasure grounds), but the specific name is lost; and I may also mention that there is a bush of Mistletoe growing out of one of the standard Apple trees in the kitchen garden about 2½ feet in diameter, produced from seeds inserted in the bark about twelve or thirteen years since by my predecessor. The tree is about twenty years old from the graft. And as to the question of injury to the tree on account of the Mistletoe, I can affirm, as far as this instance is concerned, that the branch on which it is growing is the most luxuriant and healthy on the tree; how it may hereafter affect the tree remains to be seen. As to the Limes and Whitethorns more especially, I can say we have some trees in the park so smothered with the parasitic growth, that at first sight it is almost difficult to determine which is the parent plant by looking at the upper portions only.—H. W. WARREN, *Gardener to the Earl of Portsmouth, Whitechurch, Hants.*

EUCALYPTUS GLOBULUS.—In your paper of the 6th I see reference is made to this tree. At the Mooka Iron Mines, twenty miles inland from Bona in Algeria, it was first planted eight years ago, and with such beneficial effects that fever is reduced very considerably. The foreman who showed me over the works said that they had not above one case of fever now when formerly they had four. The consequence is that the company are planting it by the million. Another benefit is

said to belong to it—viz., that mosquitos will not come within its influence.—H. T. H.

MR. PEARSON'S NEW PELARGONIUMS OF 1876.

It makes no difference whether one visits Chilwell on the 24th of June or the 21st of December, the Pelargoniums will always be found most attractively in bloom. It is impossible without seeing them to form any conception of the gorgeous display which they make massed together. They bloom as profusely throughout the whole winter as the summer. I have seen them in nearly every month of the year, and if they look better at one time than another it is in the very shortest days of the year. Most other flowers then, or at any time, will pale before them, and it is difficult to say what their greatest recommendation is. Probably it is their easy culture, coupled with the extraordinary quality of flowers they give as compensation for the little attention they require. There is nothing exacting in their cultivation, nor is there any "secret" brought to work on them at Chilwell. Common everyday fare to which they may be treated in the hands of anyone is what they thrive on. Large quantities of cuttings are rooted at Chilwell in the autumn, and potted singly into 8-inch pots in a mixture of loam and sand, and set on stages about 8 feet from the ground. Very little fire heat is used, unless to exclude frost or expel damp: under this treatment they bloom amazingly. Sometimes old plants are allowed to flower for eight and ten months incessantly, and at other times the plants are cut down as quickly as they grow to supply young plants.

It is a great mistake in amateurs with limited time and accommodation putting themselves to no end of trouble and anxiety to keep a few semi-hardy plants in existence throughout the winter, when they might have their greenhouses replete with healthy Pelargoniums and abundance of every existing shade of flower with no inconvenience whatever. Some may think and others may take the liberty of saying it would be a tame affair—a houseful of Pelargoniums, but in this I beg to differ, and it is infinitely more preferable to see an entire houseful of Pelargoniums nicely in flower than rows of barely-furnished plants.

Those who are familiar with all the Pelargoniums which have been sent out from Chilwell, especially those introduced last year, will know that to excel Lady Byron, Ethel, Mrs. Vickers, Brutus, Sir S. H. and Lady Soudamore, Stanhope, A. Henderson, Laura, Little Carr, Mrs. Jacoby, and others, will be an accomplishment which is attained in those being issued this year for the first time.

Amongst scarlets Wordsworth, Havelock, and Lord Zetland are superior to Corsair, Veuvius, or any other of this shade. Leopard is a beautiful somewhat striated salmon colour; and amongst that beautiful shade pink Lady Sheffield is excellent, and so is Sybil Holden, Mrs. Lancaster, and Louisa. For many a day Amaranth was my favourite pink, and after that I gave preference to Mrs. Gibbons, and finally Annie Orton, but these I unregretfully relinquish in favour of any or all the four I have just named. E. Davis is a splendid purple crimson variety in the way of Earl Mansvers. Mary Pearson is a beautiful rose colour, and Mrs. Gregory is of the same hue, both producing large compact trusses. Captain Holden and Frederick William bear some resemblance to the two last named, but they are about three shades deeper in colour; and last but not least comes David Thomson, which is a splendid crimson variety, the individual blooms and trusses being of immense size and of great substance, and in no way creditable to the worthy author of the "Handbook on the Flower Garden."

Before finishing let me say that amongst older varieties of the Chilwell strain the Rev. T. F. Penn is a crimson of great merit, alike useful in a pot or bed and an excellent winter bloomer.—J. MUIR, *Lenton.*

THE ROYAL AQUARIUM AND SUMMER AND WINTER GARDEN.

UNDER the auspices of Royalty and a clear spring-like day this imposing building was declared "open" on the 22nd inst. It was a happy idea of Mr. Wybrow Robertson to supplant a block of incongruous buildings by a palatial structure in the immediate neighbourhood of the Houses of Parliament and Westminster Abbey, and completing a trio of public edifices eminently worthy of a nation's patronage. No sooner was the

idea promulgated than energetic measures were taken to carry it into effect, and within a year Westminster was provided with a Crystal Palace of its own, and in the place of dirt and equalor bloomed bright and beautiful flowers relieved by stately Ferns and tropical plants, transforming a veritable desert into a literal garden by the magic wand of energy and taste.

The building, of which the Palace at Sydenham is the natural prototype, is founded on purely gardening lines laid down by our great representative of mechanico-horticultural genius Sir Joseph Paxton. The edifice is also for gardening, for it is to be kept "ever green and ever gay" by our present master of the art of floral decoration, Mr. John Wills. It has thus a direct claim to our notice, and both in its aims and objects, and the mode of carrying them out, it has our wishes for its success.

The edifice is imposing, the body consisting of a large promenade or conservatory wherein plants are grouped—the sides being occupied by the rock-bound tanks, while above them the surrounding gallery is devoted to pictures and works of art; added to these attractions is a concert-hall and reading-room. Thus the gratification of every sense is provided for, and the treasures of sea and land and intellect are or will be spread under the gigantic crystal roof.

The building is 600 feet in length, the conservatory or promenade being 340 feet by 160 feet, and an entrance hall 186 feet by 80 feet, with other accessories. The roof of the principal avenue is of iron and glass, and is glazed on the principle patented by Mr. Rendle, no putty being used or metal exposed to the weather. The tanks are 260 feet by 53 feet, and will contain 800,000 gallons of water, which by a system of oxygenising will be preserved in a state of purity for an indefinite period.

For the occasion of the opening Mr. Wills had made the garden a verity (the tanks being unoccupied) by the disposition of upwards of 20,000 plants. These were disposed in groups along the sides of the hall and at the base of three fountains, at the orchestra front, and with some choice gems fringing the Royal pavilion. These plants were not crowded or formally arranged with the "highest at the back." The beds surrounding the fount were carpeted with *Lycopodium denticulatum*, in which were plunged irregular groups of Hyacinths, Tulips, Primulas, Cyclamens, and Lilies of the Valley in profusion; the taller plants, which were thinly dotted, consisting of Dracenas, Musas, Aloesias, Richardias, Pandanus, Palms, &c. At the front of the orchestra was a fringe of *Isolepis gracilis* and Ferns, enlivened with Heaths, Primulas, *Imantophyllums*, &c., and relieved with Palms.

The fringe of the Royal box was exceedingly chaste and effective, the groundwork being composed of Lycopods and *Adiantum farleyense*, and brightened by graceful sprays of Orchids—*Odontoglossum Alexandræ*, *Phalenopsis Schilleriana* and *amabilis*, *Cypripediums*, &c.; the taller plants consisting of the most elegant of all Palms *Cocos Weddelliana*. There were also groups of Dicksonias and large Palms, Camellias and other ornamental plants in great variety.

From the galleries were suspended hanging baskets, both large and numerous, these being filled principally with Palms and fringed with Ivies and Vines. In a word they were green, and properly so, as affording an agreeable and acceptable relief to the red, mauve, and gold which prevail as the permanent decorations of the building. Mr. Wills' stand was most attractive by an array of artistically-arranged bouquets of Camellias, Orchids, Azaleas, Lilacs, Lilies, &c., associated in the "highest style of art."

On the conclusion of the ceremonial His Royal Highness the Duke of Edinburgh sent for Mr. Wills, and expressed to him his great satisfaction with the floral decorations made on that occasion. The first day's success was an augury of the permanent success which we trust will attend this laudable undertaking.

NOTES AND GLEANINGS.

We have inspected, with much pleasure, the honours won at the late Cologne Exhibition by the eminent hot-water engineers, Messrs. JOHN WEEKS & Co., King's Road, Chelsea. This gratifying recognition of British enterprise in the cause of horticulture is conveyed in the form of an imposing DIPLOMA bearing a donation of 1000 marks (£50), and is accompanied by a massive GOLD MEDAL. The diploma, which measures 2 feet 6 inches by 2 feet, is produced in a highly artistic manner, illustrative of the different phases of horti-

culture and the allied arts, as sculpture, mechanics, literature, &c. The gold medal, which is 2 inches in diameter, bears the profile and superscription, "Kronprinz Friedrich Wilhelm, Protector," and on the obverse the Royal arms and circlet, "Angusta protectorin der Flora Internationale Gartenbauausstellung zu Ooeln." Messrs. Weeks are to be congratulated on their meritorious achievement.

— We have sent to us by a friend a letter, dated March 14th, 1821, from T. A. KNIGHT, Esq., first President of the Royal Horticultural Society, and the well-known pomologist. The letter has not been published, and we take from it the following extract:—"I have also added grafts of a few varieties of Pears, some of which are probably quite unknown to you; and indeed have not borne in this country till the present year. No. 1 is Napoleon, a large Pear, which ripens from November to Christmas. I have seen it only on a wall, but it will blossom early as an espalier, and if it will bear, it will be found to possess great merit. No. 45, Marie Louise, season December, a most admirable variety, much superior, I think, to any we are possessed, but whether it will succeed without a wall I cannot say. No. 17, Caspiomont, season October and November, of rapid growth and much disposition to bear as a wall tree, and its blossoms appear hardy. An excellent variety. No. 15, Passe Colmar. I think this by far the most valuable Pear I ever have seen. Its blossoms on a wall are extremely hardy, and the variety there is productive to an injurious extent. I believe it will succeed as a standard in your climate very well. Season March and April. The four following varieties—Nos. 2, 3, 4, and 5—are for standard trees solely. No. 2 is a cross between the Jargonelle and Autumn Bergamot. The tree bore last autumn for the first time, having exercised my patience for nineteen years. Its form and size are what might have been anticipated from its parents. The Horticultural Society pronounced it excellent. Season November to Christmas. The flesh is perfectly beurée." No. 3 is new also, but bore in the autumn of 1819. The fruit remained quite sound till May, when it became what the French call demi-beurée. Some friends who dined with me at that period thought it very good; and I thought it so for the season. The tree appears a very free bearer. No. 4 is the Elton, the best Pear, I think, of its season, if gathered about ten days before it is eaten, and before it is quite ripe. Season the end of September; and if the crop be gathered in succession it may be brought to table in equal perfection, or nearly so, for six weeks. It is quite worthless if trained to a wall. It is always without seeds or internal cavity. No. 5 is the Aston Town, an excellent variety, which succeeds well as a standard tree; but the trees do not bear till their branches become pendent, and therefore should be made pendent by art. I send graft of one variety of winter dessert Apple, the best I know—the Gilliflower. Season, all winter."

— THE Royal Horticultural Society of Ireland has fixed its EXHIBITIONS to be held on April 27th, May 18th, June 29th, August 31st, and November 9th.

— ONE of the celebrities of Fleet Street was ISAAC WALTON. He lived at the house now the third from Chancery Lane going to Temple Bar. It is now tenanted by a jeweller, but Walton was a linen-draper. He is further connected with Fleet Street by having in 1652 as the publisher of his "The Compleat Angler," "Rich. Marriot, in S. Dunstan's Churchyard." We welcome the fac-simile reprint of that first edition just published by Mr. Elliot Stock, Paternoster Row, and commend it to purchasers as a literary curiosity. It is far more Waltonish than recent editions—more brief and racy. We will only quote one passage, discussed in these pages some years since.

"So I the fields and meadows green may view,
And dally by fresh rivers walk at will,
Among the Daisies and the Violets blue,
Red Hyacinth, and yellow Daffodil,
Purple Narcissus, like the morning rays,
Pale Gandergrass and asure Culverkeys."

No one has detected the plant known then, probably in Staffordshire, where Walton was born and resided when he became an author, but we must note down a jocular reply.

"Culverkeys—Culverkeys—
Why they are pigeon Peas."

There is some reason as well as rhyme there—*Culver* was the Anglo-Saxon for a pigeon, and *key* is a seed vessel, and the flowers of Vetches are blue, "azure." The wild pigeons feed on the Vetches, which are of the same natural order as

* This cross was afterwards named Tillington.

the Pea. The Tufted Vetch (*Vicia cracca*) is called in Gaelic *Peasair-luch na coille*.

— We regret to have to announce the death of M. JEAN-LAURENT JAMIN, formerly the eminent nurseryman of Bourgl-la-Reine, whose name is "familiar as a household word" to all horticulturists. M. Jamin was in his eighty-third year, and will be greatly regretted by a wide circle of friends. As a pomologist M. Jamin took high rank.

THE SYCAMORE.

THE name is literally "The Fig-Mulberry Tree," *syke* being the Greek for a Fig tree, and *moron* for the Black Mulberry. The name was applied to the true Sycamore (*Ficus Sycamorus*), the fruit of which is a Fig, and the leaves are like those of the Mulberry. The botanical name, *Acer pseudo-platanus*, Mook Plane Maple, shows that our Sycamore belongs to the Maple genus, and much resembles the Plane tree.

It is a native of mountainous districts of Germany, Italy, and other parts of Europe. The date of its introduction into England is not known, but we have the negative evidence that it was between the years 1596 and 1638, that Gerard does not

but flowers several years sooner, sometimes even perfecting its seeds sooner also. The longevity of the tree is from a hundred and forty to two hundred years, though it has been known of a much greater age. The wood weighs per cubic foot, newly cut, 64 lbs.; half-dry, 56 lbs.; dry, 48 lbs. It loses in drying about a twelfth part of its bulk. When the tree is young it is white, but as the tree gets older the wood becomes a little yellow, and often brown, especially towards the heart. It is compact and firm without being very hard, of a fine grain, sometimes veined, susceptible of a high polish, and easily worked either on the bench or in the turning-lathe. It does not warp, and is not likely to be attacked by worms. It is used in joinery, and turnery, and cabinet-making, by musical instrument makers, for cider presses, and sometimes for gun stocks. Formerly, when wooden dishes and spoons were more used than they are at present, it was much in demand, especially in Scotland, by the manufacturers of these articles. As underwood the Sycamore shoots freely from the stool to the age of eighty or a hundred years. As a timber tree it is most advantageously cut down at the age of eighty years, or from that age to a hundred. As an ornamental tree it produces the best effect either singly or in groups of two or three, placed

Fig. 19.—THE SYCAMORE.

mention it in his "Herbal" in the year first named, but it is mentioned in the edition of the year last named.

It is a very ornamental tree, and is also useful as a shelter, for prevailing winds, however strong, do not bend it from a perpendicular growth, nor is it injured by the sea spray. An objection is that its leaves at all periods of their growth are especially liable to exude a portion of their saccharine sap, which is known as "honeydew."

The colours of the foliage and seed vessels vary so much according to the time of their growth and decay as to attract a poet's notice. Cowper wrote—

"The Sycamore, capricious in attire;
Now green, now tawny, and ere autumn yet
Has changed the woods, in scarlet honours bright."

The sap is so saccharine that sugar has been extracted from it, but not in quantity sufficient to render the extraction profitable; 116 lbs. of sap would yield only 1 lb. of sugar. That obtained was like common brown sugar, but having a different flavour.

It rarely attains a height of 80 feet. Loudon says of it:—"The growth is very rapid compared with that of most other species of *Acer*, particularly when it is in a deep, free, rich soil, and in a mild climate. It arrives at its full growth in fifty or sixty years, but it requires to be eighty or a hundred years old before its wood arrives at perfection. In marshy soil or in dry sand, and even on chalk, the tree never attains any size. It produces fertile seeds at the age of twenty years,

sufficiently near to form a whole, but not so as to touch each other, and in rows or avenues."

We have observed that rabbits seldom eat the bark of young Sycamores, and have succeeded in establishing a plantation of them when most other trees were destroyed by the "vermin" within a week of being planted.

APHELANDRA AURANTIACA ROEHLII FROM SEED.

I AM informed by a gardener that the most easy and certain way of raising a stock of this stove plant is by sowing the seed in heat in the spring and growing the plants similarly to Cookscombs; but the *Aphelandras* do not require to be frequently shifted, and the soil best suited to them is peat, leaf mould, and silver sand, with a slight addition of loam.

I have hitherto grown these plants from cuttings, and while I have been frequently dissatisfied with their slow growth, their brilliant flowers have generally afforded me ample recompense.

My informant has stated that not only do these plants grow with the greatest freedom when raised from seed, but that the plants will flower the same season if not stopped, and will be found in their small state most useful as autumnal decorative plants both for the conservatory and for ornamental receptacles in the drawing-room. He assures me of their certainty of

flowering the first year, and has given me some seed which I intend shall be proved.

Before testing the correctness of the statement I name it at a period enabling others to try this mode of culture, for a supply of small healthy flowering plants cannot fail to be most valuable in hundreds of gardens.

The plants when not stopped for flowering the same season require to be potted rather deeply, giving small shifts from thumbs onwards to 5-inch pots; miniature plants, however, flowering freely in 3-inch pots. Other plants should be stopped for making larger specimens the following season. The plants require brisk top and bottom heat, plenty of light and copious supplies of water in their growing season, including frequent syringings. The plan is worthy of a trial, for if it fails the loss will be small, while if it succeeds the gain will be great.—R. H. S.

MUSSÆNDA FRONDOSA.

UNDER the above name I have for some years cultivated plants which have never failed being admired by those for whom they were provided and their many visitors. The plants, which have flowered throughout the winter and during the early spring months, have afforded a fine contrast to the effect produced by the Poinsettias.

Like the Poinsettias, the Mussændas are not ornamental by their flowers so much as by the bracts accompanying them. In the former plants these bracts are rich scarlet, in the latter pure white. The plants are altogether smaller than the Poinsettias in habit, foliage, and flower heads; yet I have frequently had pure white discs of Mussændas 8 inches in diameter, and when half a dozen of these are produced on one plant the effect is something to be admired.

But these plants are not of the easiest culture, and hence it is, perhaps, that they are so seldom seen in gardens. They are stove plants, requiring much the same treatment as Gardenias, to which they are allied, both genera belonging to the natural order Cinchonaceæ. Yet the Mussændas require more closely pruning than Gardenias; but I have invariably had the finest heads from young plants which have been treated as follows:

Select healthy cuttings of the young spring growth, but not too soft, and strike them in sand in brisk heat. Pot them off when rooted in small pots, using peat and a free admixture of silver sand. Plunge the pots in bottom heat and syringe the plants freely. Shift-on as required, using loam with the peat when the plants have attained strength. Stop them once or twice, but not after July. I have occasionally struck five cuttings in a pot, and shifted them on without separating the plants, obtaining thereby good heads, but sacrificing compact habit.

During the growing season the plants require brisk heat, a moist atmosphere, and plenty of light. Until the pots are filled with roots they should be plunged in bottom heat, and after that period they should be placed on a shelf in the stove as near the glass as possible to prevent the plants being drawn. After blooming they should be rested, and subsequently cut down, starting them again in heat and renewing their soil; but young plants are the best.—W. J. B.

FLOWERS IN THE NORTH.

Now that the winter appears to be gone we are having some lovely bracing breezes from the west and the rays of old Sol to cheer us. We feel braced up for fresh action with a rise in temperature of some 12° or 14°, and are anticipating the spring. We have a few lingering tokens left us of the past year in the shape of hardy Perpetual Roses, and the old friend Gloire de Dijon gives us a few buds yet, and the Christmas Rose is still affording us pleasure in the sunshine and for bouquets, and the *Jasminum nudiflorum* is gay as gay can be at this season. The old monthly China Rose affords us nice buds for a variety of purposes. *Forsythia viridissima* is no way behind with its lovely yellow blooms; a few stray blooms of *Cydonia japonica*, too, are very desirable at this midwinter season.

Then we are in possession of some of the harbingers of spring. The Winter Aconite is in bloom; the Snowdrops are peeping; the *Salix* is pushing on for Palm Sun-tide; the *Cyclamens* with their beautiful foliage, flowers in themselves; the *Daphne mezereum* almost tempted to break forth; the Daisy peeping up among the grass; the Dandelion half afraid to show his face to the sun; Primroses greeting us with their cheerful presence; the Bearsfoot rearing up its head in its

wilderness home; a stray shoot of *Alyssum saxatile* giving us a few blooms; Violets, too, are doing us good service in a sunny corner, with other of our old favourites, telling us to anticipate the spring.—M. H., Bedale, Yorkshire.

GROS COLMAN GRAPE.

PERMIT me to thank your correspondents for detailing their experience with this fine-looking Grape.

My object was to test its merits as to quality. I am glad to note that in this respect it has proved better than I had anticipated. My experience of the Grape was limited to cool treatment, and the fruit was not good, and when I have tested it in half a dozen gardens under similar treatment I have always found it deficient in flavour. This, it would appear, was because it required more heat to bring out its good qualities, for in every instance where it has proved satisfactory the Vines have received Muscat treatment.

A fair amount of evidence is now furnished that Gros Colman is worthy of cultivation if heat can be afforded to perfect its fruit. It is, besides being a good keeper, one of the most imposing of black Grapes, and, especially for market purposes, will produce most tempting fruit.

It ought also to be of good quality, or it should not have taken first honours at the great Show at South Kensington, where I read of its beating "splendid fruit" of Lady Downes's from Mr. Kniller of Malahanger Park, and Mr. Coleman of Eastnor Castle. As neither those growers nor the sort they exhibited is easily beaten, Mr. Wildsmith must have had something more than appearance to have turned the scale in his favour with Gros Colman.

Although it is exceedingly easy to err in arriving at a conclusion too hastily, yet the testimony forthcoming would seem to warrant at least one Vine being tested in every well-heated vinery where a variety of Grapes are not objected to, and it is equally evident that Gros Colman will not perfect its fruit in a low temperature.—EX-EXHIBITOR.

PEARS AND THEIR CULTURE.—No. 1.

THE culture of Pears is beset with few difficulties which may not be overcome by ordinary care and painstaking. True it is that some delicate sorts are materially affected by climate and soil, yet really good kinds are so numerous that it is quite possible to make a good selection for everyone and everywhere in this country.

The stocks upon which Pears are grafted often exercise greater influence upon the growth and fruit than either climate or soil. Nurserymen are fully aware of this, and those with whom fruit trees are a speciality take especial care to graft each kind upon a suitable stock—thus we find preference given to the Quince for one kind, another is found to answer best upon the Pear, and others again require a system of double grafting. I have numerous examples of each kind, the flourishing condition of which, and the excellent fruit that many of them have produced, affords ample proof of the fitness of the stocks and the soundness of the judgment exercised in their selection.

The most useful, and therefore the best, forms for trained Pear trees are the pyramidal for orchards and the quarters of a fruit garden; a modified form of the horizontal, derived from the French and termed *Palmette Verrier*, for walls and espaliers; and cordons for the same purpose. We are now so familiar with cordons and pyramids that any explanatory notes about them are unnecessary. I have not yet met with any good examples of the *Palmette Verrier*, and therefore call especial attention to it as the best combination of vertical and horizontal training I have seen. It is a hint from nature applied to practice in the happiest manner, meeting and entirely overcoming the well-worn objection taken to the excessive vigour of the upper branches of trees trained horizontally. The sketch which I append (fig. 20) will make this so plain as to render description quite unnecessary, and I need only add that the lower branches must have a good start so as to reach the highest point of growth simultaneously with the others.

Apart from its great and general utility the Pear has several properties which especially commend it to the connoisseur. The melting juicy flesh, with its rich flavour and tempting aroma, full and pronounced in some, and ranging through many degrees of delicacy in others; and the singular manner in which these and all its higher qualities are subject to local influences,

imparts a tinge of uncertainty to its culture which makes it very interesting.

The subtle qualities which are combined in a first-class fruit, and which the educated palate so much delights in, are also materially affected by the management of the fruit after it is gathered. Let us not forget this last point, for it is one of much importance, a few degrees more or less of temperature affecting the fruit so much that it is in our power to accelerate or retard the period of ripening of many kinds by several weeks; some, indeed, will not ripen at all in our unheated fruit shed. Moreover, it is surprising how wonderfully a warm room will promote the development of aroma and saccharine matter even in ripe fruit which is taken into it from a cold fruit room. Granting the truth of all this, one very naturally is led to ask, Would it not tend to simplify matters if the fruit store itself was heated? But this is objectionable, for the obvious reason that it is desirable to retard the ripening of much of the fruit to maintain a supply as long as possible; a shelf or two in any apartment where a fire is kept in the daytime, affording ample space for successive relays of fruit for immediate use.

The ripening of the fruit and the length of time it will continue good after it is ripe, is also much influenced by the time and manner of gathering it. The early summer kinds should never be suffered to ripen on the tree, but be gathered just as faint traces of changing colour betoken approaching maturity. My own plan is to devote an hour as frequently as possible on fine afternoons to looking over the Pear trees, making several gatherings of each crop, and thus materially prolonging the season even of the little Doyenne d'Été and Citron des Carmes. Of course it will be understood that the duration of these and other early Pears in prime condition must necessarily be brief under the most favourable conditions. Let there be no misconception about this matter. I have known much annoyance to arise from Jargonelles sent to table fully ripe remaining untouched for several days, and then, of course, proving mealy, insipid, and decayed at the core.

Later autumn and winter kinds require equal care. No reliable time can be given for gathering, the earliness or lateness of the season being our best guide. We must take especial care not to gather late Pears too soon. If the fruit parts readily from the branch as it is lifted upwards it is fit

Fig. 30.—PALMETTE VERRINE.]

for storing, and not otherwise. Do not suppose that because some portion of a crop falls that the remainder should be gathered forthwith. Take, for example, that excellent Pear Knight's Monarch, so notorious for its proneness to shed much of its fruit, and yet if we were to press forward the gathering it would be against the dictates of experience and good sense, the unfallen fruit clinging to the branches with such tenacity that most of the stalks will break asunder rather than yield before Nature has given her finishing touch to the fruit. Neither let an early frost or two induce you to take the fruit from the trees prematurely; wait patiently till its hold is so far loosened that it comes away as Nature intended, and you will be well rewarded by fruit of the best quality, sound and excellent in every respect.

Some difference of opinion exists about the cause of that cracking of the fruit which often seriously affects some delicate sorts. Closely examine a crop that is so affected, and you will find it is the fruit near the ends of the boughs which suffers most, and that much of it in the interior of the tree is quite sound, thus plainly showing that it is caused by the exposure of the fruit to cold cutting winds while it is swelling and when its skin is sensitive and tender. A sheltered situation or the protection of walls are the best remedies; portable screens

might also be used with good effect. It is my intention to try some such means for saving the next crop of Red Doyenné, Doyenné Defais, and two or three other first-class sorts which always suffer from this disease.—EDWARD LUCKHURST.

TUBEROUS-ROOTED BEGONIAS.

To Messrs. Veitch & Sons of the Royal Nurseries, Chelsea, and Mr. Louis Van Houtte of the Royal Nurseries, Ghent, the horticultural world is mainly indebted for this valuable class of summer-flowering plants. Their free-growing and flowering capacities, their elegant habits, and varying yet brilliant colours, are a combination of qualities only possessed by our most popular plants, as Pelargoniums, Fuchsias, &c. The new varieties of Begonias which have originated in the two great establishments referred to may justly rank amongst the most useful introductions of recent years.

In the spring, autumn, and even during the winter months, it is not difficult to have conservatories and greenhouses gay with flowering plants; but in the summer months these structures are seldom so satisfactorily furnished as we could desire them to be. Pelargoniums, it is true, of the zonal type are almost continually blooming, and their variety is

rich and their colours are varied; but these plants are so fully represented in the beds and borders of the garden in summer that their effect in the conservatory is proportionately diminished. For indoor decoration during the summer months the ordinary occupants of our stoves, such as Ferns and fine-foliaged plants, are appropriate, and with these plants Pelargoniums do not associate well, but exceedingly suitable are the Begonias now under notice. How effectively they blend with such plants as Palms, Dracenas, Ferns, &c., was demonstrated by Messrs. Veitch in their splendid group of plants at the great exhibition at South Kensington last year.

Considering the rapid increase in the number of varieties of

these Begonias, their extreme usefulness, and their promise of culminating in a hardier race than other types of this genus, is it not an oversight not offering prizes for them, both for the best cultivated plants and the best new varieties? At the great summer exhibitions prizes are provided for Pelargoniums, Fuchsias, Lilioms, Clematisses, Hydrangeas, &c., while no place is found for these Begonias, which are so intrinsically beautiful and so hopeful of producing varieties of still greater value.

Having seen these Begonias "at home" both in the Chelsea and Ghent establishments, and having grown some of them, I can testify to their undoubted worth for summer conservatory,

Fig. 21.—*BEGONIA VESUVIUS*.

greenhouse, and even garden decoration, for, if not absolutely hardy, many of the varieties are sufficiently so to flourish in the flower garden during the summer months. I shall not soon forget the collection of these plants which I saw growing and flowering in the open air at Ghent. The sorts were Agate, Cornaline, Emeraude, Onyx, Rubis, Saphir, and Topaz. Gems, indeed, I thought them, bright, varied, and sufficiently hardy to receive the names which had been given them by the raisers. Since then I believe that Mr. Van Houtte has made still greater improvements, and for some of the varieties has received the gold medal at one of the continental exhibitions.

Equally worthy of recognition are the varieties which have been raised at Chelsea, if, indeed, they do not surpass any other sorts extant. In colour, substance, and profusion of bloom, habit, and hardiness, such sorts as Stella and Vesuvius have few rivals. Both these have received first-class certifi-

cates, the plant of the last-named variety being potted from the open ground for the purpose of being exhibited.

Plants of this type of Begonias were also planted out in Battersea Park last year, and although the summer was by no means a tropical one they grew freely, flowered well, and had many admirers.

Plants, it will be readily perceived, that are amenable to that mode of treatment are not miffy or tender, but are such as are not beyond the means of those who do not rejoice in pretentious gardens with every appointed means for growing tropical plants. A dung frame for starting the plants, and other frames heated by the sun for growing them on, are the only structures really necessary, and which will produce plants most attractive for conservatory or room decoration in the summer and autumn months. The varieties are very dissimilar, as may be perceived by comparing the engraving given

of *B. Veauvius* with one of *B. Stella*, which, with some cultural notes, will appear in a future issue.

The great merits of this free and beautiful race of *Begonias* entitle the plants to be cultivated extensively. They should be as familiar in conservatories during the summer months as are *Pelargoniums* in flower gardens.—W.

GROS COLMAN GRAPE—HAWTHORNDEN APPLE.

YOUR correspondent "EX-EXHIBITOR" invites experienced growers of Gros Colman Grapes in a cool vinery to state their opinion respecting their flavour. I have grown the Vine in a vinery without a stove for many years. We are situated nearly 500 feet above the sea, and in the mountains, where we have more than a usual share of sunless days. Two years the Gros Colman failed to ripen so as to be eatable; but for some seven or eight years it has ripened and coloured fairly. I recollect it was remarked one season that it had an "earthy" taste; but I should characterise it rather as flavourless than as having any bad taste, and it is such a vigorous healthy Vine, so good a bearer, and such an ornament to a dessert, that I do not grudge its room, even in my own limited space. In regard to "EX-EXHIBITOR's" recommendation not to grow late Grapes in a cool vinery, I can only say I have had Mrs. Pinco's Black Muscat for many years, and it has never failed to produce an abundant crop, and both to colour and ripen well.

In looking over the new edition of Dr. Hogg's "Fruit Manual," I observe that he especially recommends the Hawthornden Apple as one always healthy and vigorous, and not subject to canker. Now, my experience of it is totally different. I have tried it for many years, and, admiring its useful qualities, have distributed plants of it among the cottagers in my neighbourhood, with one uniform result—i.e., destruction within a year or two of every plant by canker. I have now given it up entirely. The soil here is a light gravelly one, with a gravel subsoil. But I have noticed the same thing has occurred in other localities where a heavy and clayey soil prevailed. I may add that I have tried cutting down, paring away, and removal, to no purpose. My trees are entirely gone, and so are those of my cottage neighbours. With the exception of Ribston Pippin no other Apple cankers here.—C. R.

RANGEMORE HALL.—No. 2.

THE SEAT OF M. T. BASS, ESQ., M.P.

CONTINUING my notes on this complete and excellent garden from page 55, I will glance at the glass structures, not in a detailed manner, but as affording a general idea of the extent of the garden, and as shadowing also its sound management.

We first enter the Peach houses. The extensive ranges of houses devoted to Peaches and Nectarines are of two kinds—lean-to's, the trees being trained to back walls, and span-roofs with the trees trained on trellises. Only the latter demand a note of description. The houses are spacious and lofty, having a sharp pitch, the fruit trellises on either side extending from the ground in front to the apex of the roof overhead. The trees are not trained on the usual fan shape, but the branches are trained horizontally along the wires, similar to the mode generally adopted in training Pear trees on open walls. This mode of training Peaches under glass Mr. Bennett finds has important advantages over the orthodox system. The work of thinning and training of the shoots in summer is simplified and can be done more expeditiously, and much of the common danger of overcrowding is averted. Winter pruning is also similarly simplified, and copious waterings and rich feeding at the roots does not result in exuberant wood growth, but produces healthy trees and fine and regular crops of fruit. The trees are at first trained in the ordinary way, and when they have attained a suitable size the branches are gradually brought to the horizontal position as the permanent mode for fruit-bearing. No trees could look neater than did these. Every foot of wire was occupied, and between the lines of wire there was no useless spray, and thus every inch of space was devoted to a profitable purpose. Mr. D. Thomson trains his Fig trees in the same mode at Drumlanrig with great success, and, as is evidenced at Rangemore, the plan is equally applicable to Peach trees when cultivated under glass, and especially when the glass has a steep pitch; on flat trellises the system would, perhaps, not be so advantageous. All the standard sorts of Peaches are grown. Prince of Wales is much prized by Mr.

Bennett, and perhaps especially so is Raymaecker's, a kind which is not in general cultivation; it is a late Noblesse, and a superior sort. Barrington is considered the best late variety, and is superior to Lord and Lady Palmerston, which are not proving so good as was expected.

Peaches are also to some extent grown on the open walls, and I notice one wall 100 yards in length covered with these trees, and Apricots, to show the simple and efficient mode of protecting the trees on the wall and tender plants on the border by the same set of lights. It is a sort of home-made contrivance, and answers its purpose admirably. The wall is about 15 feet high, and the border about 14 feet wide. On the latter is fixed a continuous box or frame covering the entire border save about 4 feet nearest the wall. At that distance from the wall and parallel with it is fixed the back of the frame, posts being fixed in the ground at convenient intervals, with boards from post to post, some of them opening as shutters to admit air. The back of the frame is about 3 feet in height, the front about 18 inches. Rafters are fixed to support the lights, which are about 9 feet in length. This huge frame is crowded to repletion during the winter with Lettuces, Endive, Cauliflowers, Parsley, and innumerable other plants which need some protection against the severity of the weather. On the approach of spring the lights are no longer needed over these plants, but the trees, which are just then opening their blossoms, need protection, and the lights are simply pushed up, their bottoms resting on the back of the frame, and their tops under the coping of the wall, and the crop of fruit is made safe; the frame—the enclosed border—is then cropped in the ordinary manner. It is a simple and effective combination, and it is not easy to determine for which purpose the lights are the most useful, whether for preserving tender vegetables in the winter, or for protecting the fruit trees during the spring and early summer months. It is adaptable to many gardens, and is an eminently useful contrivance, easily made and not costly.

As may be expected, Grapes are required in large quantities and at all seasons, but Mr. Bennett, by the aid of the means afforded him, is, in hackneyed parlance, "equal to the occasion." For four years Rangemore has not been without Grapes. Lady Downe's Seedling generally keeps in good condition until May, and before that time Black Hamburgs are ripe to continue the supply. To this sterling sort there are four houses devoted; it is a fine range of glass 100 yards in length. The Vines in the first or earliest house are grown and fruited in pots. At the time of my visit they were being prepared for their work, and more promising canes it would be difficult to find. The Vines in the succession houses are planted out. They are six years old and in splendid condition, producing superior Grapes.

But more interesting at the end of October than the nearly empty Hamburg houses were the structures devoted to the winter supply of late Grapes. These are grown in wide and lofty span-roofed houses, the range being nearly 100 yards in length. These houses are amply heated and ventilated, and are well adapted for keeping the Grapes, and also, it must be added, for growing them, for a more regular crop of useful-sized bunches with fine and highly-finished berries is not often seen than the crop now under notice. I have had opportunities of seeing the best exhibitions of Grapes in England and Scotland, and I have not seen Lady Downe's Seedling, Black Alicante, and Muscat of Alexandria in better table condition than at Rangemore. The bunches were not "monsters," but the berries were fine and admirably finished, and for everyday dessert purposes the crop was highly creditable to Mr. Bennett and his assistants.

It also speaks volumes of the power and benefits of surface-dressing the ground with manure. The borders are mainly inside, and had been originally made with some of the unsuitable Rangemore soil. So unsuitable was this soil that on examining the roots they were found in a deplorable state, many of them being absolutely dead. Fresh material was applied to the surface of the border, and especially a very heavy covering of rich stable manure was given, and this, by inducing the emission of surface roots and affording them sustenance, has perfected a splendid crop of Grapes, which but for the rich surfacing must inevitably have been of a very moderate character. Such an example as is afforded by these Vines of the great value of top-dressing the borders with rich manure is of the most conclusive kind, and the practice cannot be too extensively adopted. In these houses Gros Colman was striking by its huge purplish-black berries, but, unfortunately, their

flavour was the reverse of agreeable. The fruit was splendid to look at, but certainly not good to eat. The roots of the Vines have access to narrow outside borders covered with corrugated zinc roofing sheets, which are probably the neatest and most effectual of covers for keeping the borders dry, superseding felt and wooden shutters.

In making new borders Mr. Bennett finds it necessary to use concrete, but takes care that it has a sharp gradient and is in connection with an efficient system of drainage. He uses fresh loam, bones, soot, and charcoal, but the loam is light and not of a "wearing" nature, yet by enriching it with manure and in conjunction with an otherwise good system of culture this fine garden is not likely to be deficient in fine Grapes.

Pines are in great demand, and five spacious pits are devoted to their culture. They are grown in pots, the staple sort being the Smooth-leaved Cayenne. The plants, judging them by their appearance, are evidently grown under a low temperature, and it is more than probable that not an ounce of fuel is wasted over them. The fruit is not exceptionally large in itself, but is large in proportion to the plants. Applying my rule to one of the plants I found that from the soil to the base of the fruit was 9 inches, the fruit itself 9 inches, and the crown 5 inches in height—proportions which speak for themselves. In one house I noticed upwards of ninety plants of that character, so that the winter supply is not likely to be in any degree a scanty one. The succession plants were equally dwarf, sturdy, and healthy. They are generally fruited at eighteen months from inserting the suckers.

I have nothing more to add on the fruit culture at Rangemore except to notice a Fig, the "Negro Largo," which Mr. Bennett considers is one of the finest kinds in cultivation; it was sent out by Messrs. Veitch, and was carrying a heavy crop of handsome fruit of the first quality; and also to note that four thousand pots of Strawberries are forced annually, the best sorts being *Vicomtesse Hérisart* de Thury and *President*.

Of the plant-growing department I may briefly say that a lofty house with a ridge-and-furrow roof is devoted to *Camellias*, with *Maréchal Niel* and other *Roses* covering the roof—a happy idea, the *Roses* giving a profusion of grand blooms, and affording at the same time the necessary shade to the *Camellias*. The latter are planted out—huge bushes full of health and buds. An adjoining house is devoted to *Azaleas*, which are also fine plants in excellent health. At one end of this range is the Heath house, a spacious and substantial structure with stone stages, on which this class of plants thrive so well. The collection is still young, but the plants have made admirable progress and comprise all the choice varieties. This is one of the best houses at Rangemore, and the plants are worthy of the house. At the other end is the Orchid house. This also is a spacious structure, and is filled with Orchids and ornamental-foliaged plants as clean and healthy as it is possible to find them. On the roof are *Allamandas* and a fine plant of the *Vanilla aromatica* with roots 9 feet in length, and *Cissus porphyrophyllus* is effectively trained up the columns. Amongst the Orchids were noticeable some fine specimens of *Cælogryne* in variety, *Odontoglossum grande* with six spikes, and *O. Alexandræ* in extra fine form having a spike with six branchlets and twenty-five blooms. *Lælia anceps* had seven spikes and twenty-one blooms, and *Phalænopsis Schilleriana* was in remarkable luxuriance. *Calanthes* are also well and extensively grown. The above are but a few of the noteworthy specimens in this noble tropical house.

Other houses are devoted to the production of decorative and table plants, which are grown in great numbers. One house is filled with Ferns, another with *Gardenias*, and others with mixed collections of ornamental-foliage plants, amongst which was blooming a splendid specimen of *Cochlostema Jacobiana*. This superb plant is not unlike a huge specimen of the Bird's-nest Fern. Many of the leaves are 4 feet in length and 4 inches in breadth, sheathed at the base and pointed at the apex. From the axils of the leaves the flower-spikes appear. The flowers are rich blue and violet, and are associated with pinkish bracts. For cut blooms they are extremely beautiful, and the plant is most striking and attractive; it has been flowering freely throughout the summer, and is worthy of special notice.

As affording an idea of the extent of the decorative plants required at Rangemore, it may be stated that 1600 Roman Hyacinths are forced, upwards of 600 Dutch Hyacinths, 1200 Crocuses, and other bulbs and forcing plants are provided on the same extensive scale.

The kitchen gardens are well cropped and are uniformly neat, the same care being devoted outside that is so evident under glass. The demand for vegetables forced as well as unforced is very great, and to meet it twelve dozen Cauliflowers must be cut weekly throughout the month of January. Mushrooms are always in demand, and the demand is met; for, save by one failure of spawn, Mushrooms have been out every day for thirteen years. As will be seen, the post of manager here is no sinecure; but in proportion to the skill displayed so is the recompense of the gardener, for Mr. Bass is proverbially studious to reward all in his service who are worthy, and this reward Mr. Bennett has won by his sound practice and assiduous attention.

A notice of this place and the liberal provision which is made by Mr. Bass for his own requirements would be incomplete without a record of his care for the comforts and well-being of his dependants. The gardener's cottage is a model of what such a cottage should be—pleasant, commodious, with every appurtenance to make it convenient, and its occupants feel that it is a home to care for and to cherish. The rooms for the ten young men are also of the most approved kind, each man having a separate bedroom and wardrobe, the foreman further having a separate private room. There is the common dining-room, also a library furnished with books and seven periodicals, including all the gardening papers, and two female attendants are provided to see that the wants of the men are supplied in a proper manner. Surely such privileges demand in return hearty and faithful services, and an active interest in all that pertains to their several duties. They should feel, too, that the credit and reputation of Rangemore is in their keeping, and strive to make themselves proficient in the different branches of their calling.

Further than this care of a liberal employer is this other noble fact, that when by misfortune or old age a man can no longer labour, he is still enabled to live on the system of pensions proportionate to the value of his services. To comment on that generous provision of a generous mind and affluent gentleman were to "gild refined gold," and it may worthily close the notice of this complete and well-managed garden—a garden which everywhere bears the impress of taste and care on the part of the owner and ability on the part of the gardener. The immediate superintendence of Rangemore devolves on Mr. Arthur Bass, M.P., who is a great patron of horticulture, and who inherits the business aptitude, also the kindness and benevolence, which have for so long been attached to the name which he holds and honours. Mr. Bennett is also young in years but old in practice, and the sequel of his success may perhaps be traced to a period of probation under the veteran Mr. Barnes of Bickton, and for a lengthy and important charge in the dual gardens of Chatsworth.

I have to thank Mr. Bennett for his courtesy and attention, and render my acknowledgements of the hospitalities of Rangemore and the shelter it afforded me when the hotels at Burton could only be reached by boat, when the lake fires were extinguished by the flood, and provisions from distant towns were hoisted into the windows of the upper rooms with pitchforks. May I never see the like again!—J. W.

GLASS COPING AND FRUIT CROP FOR 1875.

No. 1.

THE year just passed will long be remembered for its excellent crop of wall fruit, especially of Peaches and Nectarines, and to these two kinds of fruit my remarks will be principally confined. To what is to be attributed the unusually large crop of fruit in 1875? If proper attention is not paid to the trees in the year preceding we cannot ensure a heavy crop of fruit. This was shown in a very marked manner in the year 1874, during which year the wood happened to be well ripened. Prematured ripeness of the wood is sure to end in disappointment; and if we could trace the failures to their true source we should, I am persuaded, find them brought about by the want of moisture at the roots and disregard to the daily vigorous application of the syringe to keep down red spider, &c. Let drought and red spider do their work, and a proper development of buds for the next year's crop is impossible. I am led to believe that failures which may have occurred can be traced to the above causes, by seeing many trees almost quite denuded of all foliage as early as the end of August. The wood was ripe and there were plenty of bloom buds, but they were of an inferior character. The result was, that when spring arrived the buds, instead of bursting into a

fruitful blossom, were cast to the ground, or if enabled to open they were too exhausted to support and sustain the fruit.

It should be kept in mind when deciding upon the merits of glass coping, that no glass coping or protection of any kind can of itself produce a crop of fruit, and a further trial is necessary before we can judge of its efficiency. I would therefore advise those who may have failed in obtaining a crop of fruit under glass coping, if it has only been used for one season, not to condemn it at once, but give it another chance before pronouncing the coping a failure. On the other hand, I advise those who, like myself, have obtained a good crop not to be too confident in attributing their success to the glass coping used during the spring for the first time.

Coping undoubtedly plays a very great part towards giving us a crop of fruit, but I look to other agents to play an equal part. In this instance we notice that the year 1874 was unusually favourable for laying the foundation for good crops, and then the spring following was all that need be desired—mild and calm with but little frost, this mildness continuing from the time when the blossoms were expanding till the "little wee fruits" could be seen peeping through the dwindling flowers. Those trees with abundance of nourishment to feed them, and at the same time forcing-out young leaves to shelter them, were found to carry heavy crops; those, on the other hand, that produced plenty of blossom buds but the trees with health impaired, were unable to support the fruit.

It is only one more instance brought to our notice how the previous year's treatment has to do with the present year's production. I attribute my heavy crop of Peaches and Nectarines not to the glass coping and hanging nets, but principally to the good health of the trees, obtained by unremitted watering, mulching, syringing, and cleaning them through the summer and autumn of 1874. I fear many who saw my trees with such crops, and the glass coping over them, concluded the coping must have been the cause. Perhaps I might have been led away with the same idea had I not other trees quite as heavily cropped without the coping.

I think it should be generally known that glass coping in itself will not produce a crop of fruit; there must be a corresponding care to produce and keep a never-failing vigour in the tree. Starving the roots and protecting the head will avail nothing, but attention to both will do much. Is not a little more care of the wall trees and less to the flower beds occasionally advisable?—J. TAYLOR, *Hardwicke Grange*.

CULTURE OF VINES IN POTS.

ONE can scarcely enter a nursery of any note and refrain from surprise at the immense stocks which are annually provided of potted Vines and Roses. The prince of fruits and the queen of flowers are evidently popular, and there appears to be no fear of disloyalty in the minds of those who devote large houses and acres of ground in preparing a supply of potted Vines and Roses. It is to the former that I will now refer.

Potted Vines, as a rule, which are raised in the nurseries are preferable to home-raised canes, simply because in most private gardens suitable houses cannot be devoted to these Vines, and the canes cannot have the exact treatment that they require. In the few gardens affording the necessary means potted Vines are often grown in a most perfect state. I have seen them good at such places as Frogmore, Burghley, Ramsgate, &c. But in the best places home-raised canes are seldom solely relied on, but a portion are purchased from the nurseries.

But there are many who cannot purchase, yet who like a few—it may be half-a-dozen or so—of potted Vines, and these must be raised at home, and perhaps not under the most favourable conditions. Now when such Vines are grown they are generally required for early Grapes, and to produce these it is above all things necessary that the canes be grown early in the summer and the wood be ripened early in the autumn. Without these three earlier—early growth, early wood-ripening, and early rest—the fourth early, early fruit, is not attainable.

It has become popular to grow the canes from eyes and perfect them during the same season, and where houses are provided sufficiently heated and light the plan may be easily carried out, but it cannot be successful in the absence of those conditions. Those who do not start their vineries or Cucumber houses until February (and they are the majority) cannot well perfect Vines from eyes inserted in the current season, yet

that is the plan which is attempted by many, and after all the attention they give they can only half succeed. People to be successful in any work must adapt themselves to circumstances, and to succeed with Vines under the conditions named they must start now with "out backs." Small canes raised last year, cut down to the soil in early winter, and started in February, will make canes far superior to those which are raised from eyes the same season. They may, perhaps, be in 6 or 7-inch pots, and should be partly shaken out and repotted after the eyes have pushed about an inch, using warmed soil. In a proper temperature they will grow rapidly, and by the end of June will be of the length required.

If growing very freely I never hesitate to pinch the leading shoot, for another leader is formed in a few days, and the stopping "plumps" the lower buds. The best pot Vines I ever produced were stopped at 8 feet, 6 feet, and 9 feet. The Vines in their growing season must have light, and must therefore be trained as near to the glass as possible. A Cucumber pit or house is a very suitable place for raising the canes. They must be syringed freely, using occasionally perfectly clear soft water, which will invigorate them and ensure them against the attacks of insects.

After the growth is made the Vines must not be hurriedly placed in the open air to "ripen their wood," for let it be remembered that it is heat and not cold that is the prime maturing agent.

The soil best suited to Vines in pots is pure loam with a slight admixture of bone dust, say a pound of "dust" to a peck of soil, using also in the compost lumps of charcoal freely. That is all the stimulant needed in the preparing year, but in the fruiting season rich top-dressings must be applied, with supplies of liquid manure after the stoning period.—A FOREMAN.

OLD TREES.

WHEN I was at school I received a castigation, and subsequently a shilling to make me remember the "dressing." I have not forgotten it, the shilling having been an effectual memory-preserver. Mr. Robson rewards first, and then castigates—rewards by praising the completeness of my remarks on page 81, and then in an article of considerable value (page 61), demonstrates their incompleteness. But his reproof is kindly meant and kindly administered, and I will not only endeavour to remember it, but I thank him for it, his great experience and unusual means of observation on this matter being such as to command respect.

Perhaps my tutor imagines I am about to follow his example, and that after "lathering" I shall commence "shaving." Well, perhaps I shall, but nevertheless I thank him in all sincerity for his contribution, and will promise that I shall not differ from him "violently."

In one point I agree with Mr. Robson, and in another place he agrees with me; so far, therefore, we are good friends. He says that an old Apple tree should not be touched with a knife or saw during the last ten years of its life. I cordially agree. I said that thickness in the interior of old orchard trees was generally caused by thinning. Mr. Robson confirms that very clearly. But I said further, that thickly-crowded trees can be made thin by pruning and subsequently disbudding, and experience has taught me that it can be done beneficially, limiting the practice to trees in a thickly-planted orchard; trees that are singly and exposed being especially excepted.

Twenty years ago I took charge of an orchard of mixed fruits, the trees being one dense thicket, so much so that the fruit, which was small, could only be gathered with great difficulty. Mr. Robson would have removed some of the trees entirely and have left the remainder untouched. They were full-sized but not old trees. I removed some, and the others I pruned, not shortening their branches but removing many, subsequently rubbing-off the after-growths, or the trees would soon have been thicker than before. The improvement was permanent, and only last year I received the congratulations of the owner of the orchard which I "mutilated" in 1854. Of course the trees were not then in their last decade, or I would not have pruned them; neither has the treatment they received apparently shortened their days, but it has improved their fruit.

Apparently the oldest and most decrepid tree was a Ribston Pippin. It was an "old favourite," and was treated like the rest as to pruning. The crooked, curled, knotty branches were taken out, leaving only the smoothest, straightest stems, and these were not shortened. The lichens were killed. A

cartload of soil was taken from its roots and replaced with rich manure, and was soaked with a barrel of very strong "cowyard tea" and sewage. The soaking was continued annually, and the tree put forth new branches and new life, and has since produced crops of highly-coloured and richly-flavoured fruit. I have adopted the same plan with other old trees—that is, I have removed their old scraggy branches, cleaned the rest, and soaked their roots in winter or summer with strong "stuff" with the greatest benefit to the trees—thereby, I believe, lengthening not shortening their days. Mr. Robson will doubtless attribute this to the manure and not the knife, and very likely he may be right, but I think that the manure was guided into channels which would direct it more expeditiously on its strengthening mission than would have been its slower movement through innumerable snaggy paths.

But I have to grapple with my friend on grafting and killing his tree. It appears that he expected it would succumb, and preserved his new sorts by grafting them on other stocks, so that after all it appears he might have saved the tree and the new sorts too, but he preferred to kill. Probably the tree was really too old to suffer amputation, and especially in "forty or fifty" places. Suppose he had amputated in three or four places only—that is, have cut it boldly down to the main forks, it very likely instead of dying would have pushed and grown vigorously. I have seen that to be the case, while trees treated as Mr. Robson has detailed, by topping them as it were, have dwindled away. How is it? I have seen many grafts die, but rarely a healthy stock when cut boldly down.

When a tree is apparently at a standstill it is because there is not a sufficient force of sap to sustain vigour and make new foliage. The roots have lost their propelling power by the too numerous and still obstructed twisted channels dividing and exhausting the sap, and to merely "top" the branches, leaving the still impeded sap-courses, is to aggravate the disease. If a given amount of water is distributed in fifty rills its course will be sluggish, but confine it into one or two clear mains and it will turn a wheel and grind corn. If that is a far-fetched illustration I will adduce another "nearer home." There are now plenty of large Fuchsias in pots which have flowered last year; they are denuded of their foliage, and are, in fact, miniature deciduous trees. Simply top them—that is, shorten each twig or branch moderately; they will push fresh growth, probably sufficiently strong to produce the desired amount of bloom by the aid of rich food. But cut some of them boldly down—instead of mutilating in fifty places amputate in one—in fact, cut off their heads and clear away the hundred sap-courses, thus concentrating the fluid, and note its additional force. The after-growth will possess five, perhaps tenfold greater vigour than will that of the daintily-pruned plant, and the rule holds good with all plants and trees that have the power of pushing dormant buds.

Yet Mr. Robson's is a very useful letter—most willingly do I grant that, and I grant also that Apples are about the worst of all fruit trees to endure mutilation, and it is often best to amputate, otherwise "let them alone."—RADICAL CONSERVATIVE.

NOTES ON VILLA AND SUBURBAN GARDENING.

PRUNING APRICOTS, PEACHES, AND NECTARINES.—It is usual to defer the operation of pruning the above trees until all danger from frost is over. It would require an exceptionally hard frost to do the trees any permanent injury by pruning them, and the chief detriment would be at the places where the cuts were made. No doubt to expose a tender portion of surface, such as a cut would leave, in hard weather would cause the wood to die back an inch or two; and if, as in most cases, there is a wood bud and perhaps also some fruit buds at the extremity, there is then a direct loss upon what was intended at the time of pruning. This is in itself a sufficient cause for delaying the pruning of these somewhat tender trees till there is a prospect of overcoming the danger; and more especially do I think it proper or safer to delay a little after seasons similar to the last, when the wood was imperfectly ripened.

The most sappy portions of unripened shoots are apt to be blackened by the frost; and if they are left at pruning time they will disappoint by producing weakly and imperfect wood, and the flower buds are liable to drop off, to be followed probably by gumming and canker.

Now is the time at all events—unless exceedingly exceptional hard weather sets in—that the pruning of these trees may be done, beginning first with the Apricot, which is the hardiest of them and the first to come into bloom. These trees produce

much of their fruit on spurs of some years' growth, the trees also fruiting on the yearling shoots of moderate growth. The former should be spurred-in almost closely, and the latter should be cut back according to their strength and to a wood bud, which may always be distinguished by its shape, which is long and narrow, or pointed more than the fruit buds. In Apricots the buds are frequently situated in threes—two bloom buds with the wood bud in the centre; and again, it is not uncommon to find a young shoot with few if any but wood buds. There must be care in pruning or leaving these, for if they produce little else but wood in the ensuing season no object is obtained, but the strength of the tree is impaired by crowded growths.

In pruning let the face of the cut be in an opposite direction to the bud. It may not make so much difference if the cut is small, but if large the wet is carried into the bud and injury ensues. Leave the shoots at regular distances, but study the vigour and condition of the tree in every way; and if the tree is weakly prune closely, and leave the shoots farther apart than would otherwise be the case. Nothing looks so bad as to see the centre or body of the tree naked. It is scarcely possible to rectify it in after years; the tree must be well started when young, and the same system of pruning followed by whomsoever the work is done.

In Peaches and Nectarines a closer inspection must be made for the sound, ripened, and medium-sized wood. It is the fashion to lay the shoots in too thickly, for there is a twofold object in view—that is, to ensure good-sized, well-developed, and well-ripened fruit, and also to leave plenty of room to lay-in young growth to mature properly for carrying fruit the succeeding year. And again, it may not be wise to condemn a shoot all at once, or to take out an old one till there is a certainty of its place being supplied well by the succeeding one. These are matters that must be left to the discretion of the cultivator. In some parts of a tree there may not be so many shoots as are required, and those shoots that are there should be pruned well back if weak, but if strong a greater length may be allowed them; and in order that the tree should look well and be placed in the best way of filling up all parts alike, let a regulation of its branches take place by the tree being unfastened from the wall and re-nailed. Some do this every year, but in my case and many others there is not time to do it annually, but only when it is really necessary.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

Saving Seeds.—It is no part of the duty of the gardener to save seeds, nor is it profitable to do so. This work is now so well performed by the principal seedsmen, and the seeds can be obtained at such a trifling cost true to name, that it is not worth while to occupy space in the garden with them, and the ripening stalks cause the garden to look untidy. Although we do not recommend either gardeners or amateurs to save their own seeds, there may be exceptions to this in the case of those who are in possession of any new or rare vegetables, or some favourite sort that cannot be obtained in the usual way. It will not do to grow too many different varieties, especially of allied species; for instance, it would not be possible to save seeds of different members of the Brassica tribe in the same garden if they were in flower at the same time, and yet keep them free from contamination. A particular variety of Celery has been saved at Loxford for many years, and the stock has been kept true by selection. The plants intended for seed are planted out on level ground in a sheltered position; about two plants will yield a supply of seeds for several years. One sometimes meets with a selection of Cabbage, Savoy, &c., in a cottager's garden that the best commercial growers would be glad to obtain. The selection has been brought about by years of care, and it is a work of real pleasure to the owner to give a few seeds to his friends. If it is intended to save seeds of any cruciferous plants only one variety should be attempted in the same garden. Plants of the variety intended for seeds should be selected now and planted out in a good position, although it is right to say that the largest produce is obtained from stocks planted in the autumn. The seedsmen have driven us to save our own seeds the first season by charging at the high rate of 60s. a quart for their Peas in some cases.

As the Celery is cleared off, the ground is dug, and without any manuring is in excellent tilth for Onions; the ground should be dug across the trenches. As Coleworts are cut for use the ground is trenched and well manured for Peas and Beans. We have tried many varieties of the latter, but none has been found at all equal to our own stock of Windsor. The Seville Long Pod will be tried against it this year, and however this sort may be received in the kitchen it is certainly the best variety for exhibition. The pods are immense.

Tomatoes have been sown in heat of Hathaway's Excelsior and Orangefield Dwarf Prolific. This last-named sort has done us good service for pot culture every year since it has been let

cut, and notwithstanding the rival claims of Excelesior we do not like to part with good old friends. Carter's Green Gage will also be tried this year.

The Seakale has been planted for forcing next season, and seeds will be sown about the first week in March. Rhubarb has also been planted out, and Horseradish; it has been found better not to plant the crowns of the latter so deeply as formerly. The ground is well worked, and manure is placed about 18 inches deep, and the crowns are placed 8 inches below the surface.

Those who have no command of forcing-houses or even frames will have to adopt some scheming at this season to obtain early salads and vegetables. Carrots and Radishes may be sown together in a sheltered corner and under walls. Lettuces and Cauliflowers may be sown; advantage must be taken of fine days for this work. Mustard and Cress or any other small salads may be sown also. For winter salads the common Chicory is not so much used as it ought to be. A few rows sown in the garden and grown to be a good size during summer may be lifted, and successive batches taken into any forcing-house from November onwards will yield a constant supply.

Seeds of an improved Chicory, or at least a nearly allied plant, is being distributed this season. It has been known on the Continent for many years, and is there termed "Witloof," or, in plain English, "White Leaf." We have tasted this salad, and can unhesitatingly recommend it. The leaves are blanched by forcing the plant in a dark place.

PINE HOUSES.

The plants in fruiting-houses are carefully attended to as regards watering. The soil is much compressed in the pots, and owing to their being plunged the under portion retains water when that nearer the surface becomes dry, and this dryness at the surface is still further promoted by those in charge of the plants; they move the surface with a label or something which loosens it. This ought not to be done if the surface is quite loose, for by frequent stirring it is not possible to know when to water, as the loose mould becomes so dry that water passes away into the more solid parts, leaving the surface still dry. The attentive Pine-grower will soon become acquainted with the wants of each of his plants, and will know how much water to apply merely by looking at the surface of the mould. As the Pines are out we turn the plants out of the pots, and by the state of the soil are guided as to the treatment of the others still swelling or ripening off. Generally, no more water is required at the roots after the fruit shows signs of colouring. All the roots of our plants, from the smallest suckers to the fruiters, are retained in a healthy state through the winter months, and all of them have a season of as complete rest as it is possible to give them. We have a great advantage over the old growers who obtained all their bottom heat from deep beds of tan, whereas in these latter days the bottom heat can be regulated almost as easily as the temperature of the house by shallow beds over hot-water pipes.

The Pine house is also one of the best structures for bringing on Dwarf Kidney Beans early. This vegetable is prized at any season, but most of all in early spring when the Covent Garden price is 5s. for a hundred pods. We grow the plants—as has already been described in previous numbers—in 7-inch pots; and if the plants are kept healthy, and the pods are picked as soon as ready, a long succession may be had.

Strawberry plants do very well in the same house. The temperature of 65° is rather too high for them, but the plants, if kept near the glass and ventilators, and are well supplied with water at the roots, take no harm. Black Prince is the sort most to be depended upon. A few plants of Keens' Seedling will be placed in heat this week.

Young plants in the Cucumber house make but little progress as yet, and until the middle of February we do not care to have a higher night temperature than 65°; after that time, with 70° at night and a proportionate increase by day, the plants make good progress.

PLANT STOVE AND ORCHID HOUSES.

The temperature is not yet materially increased, but advantage is taken of fine weather to range the houses a few degrees higher than they were a few weeks ago, the atmosphere being only moderately charged with moisture. Stove plants, and notably Orchids, must have a season of rest during the winter months, and this is best attained by keeping them as dry at the roots and in as low a temperature as may be deemed safe. Steaming the houses we do not approve of; this practice was common at a time when plant-culture was not so well understood as it is now. Mr. Macintosh says, "Steaming the stove during winter is a material feature in the best management of such plants, and should be scrupulously attended to, both to soften the atmosphere of the house as well as to prevent the increase of insects, particularly red spider, which is sure to make its appearance in a high and dry atmosphere. The most eligible time for steaming is in the evening, when the flues are hottest, and it is performed by pouring water on them, which generates steam readily," &c. We have given up steaming

altogether, as having a tendency to weaken the constitution of the plants. Our plants are pretty free from insect pests; but those who have mealy bug, thrips, red spider, or scale in their houses should now make a vigorous onslaught against them. Patient washing with soapy water is the best way to destroy all of them; the leaves of many stove plants are tender, and in careless hands are frequently much injured.

Many stove plants are greatly benefited by a little bottom heat at this season, and those gardeners who have not the command of a tan bed cannot compete equally with those who have this advantage. Young plants of various stove plants have been repotted; the pots were well filled with healthy roots. Such as these would start much better in bottom heat, but we have not this advantage.

Some Orchids require repotting in cool and other houses. The best time to do this is when the plants begin to make fresh roots, and this may happen any month in the year. With six or eight plants a succession of flowers of *Dendrobium nobile* may be obtained from November until June, the plants at rest being kept in the greenhouse, and a plant should be placed in heat every three or four weeks. No other Orchid will stand such rough treatment as this. If it is not possible to remove Orchids in flower to a show house specially prepared for them, where the flowers would be longer retained in beauty in a cooler and drier place, they should be kept as dry as possible, and no water should be allowed to fall on the flowers.

Important additions are being annually made to our stock of winter-flowering Orchids. What in the whole range of winter flowers can surpass the glowing colour of *Masdevallia Veitchii* and *Sophranitis grandiflora*, or the chaste form of *Odontoglossum Alexandræ*, or the purity of *Oclogyne cristata* and many others? The leaves of our plants had become dusty, which tends to disease. They were washed clean with a sponge and soapy water. —J. DOUGLAS.

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

BRIGHTON (Spring Show). March 22nd and 23rd. Mr. G. Webley, Holm Wood, Westbury-upon-Trym, Hon. Sec.
ROYAL CALEDONIAN HORTICULTURAL SOCIETY. Shows April 5th, July 5th, and September 18th.
WESTMINSTER AQUARIUM. April 12th and 18th, May 10th and 11th, May 30th and 31st, July 5th and 6th, October 4th and 5th.
MAIDSTONE (ROSES). June 21st. Mr. Hubert Bensted, Rockstow, Maidstone, Sec.
SPALDING. June 21st. Mr. G. Kingston, Sec.
RICHMOND. June 29th. Mr. A. Chancellor, Hon. Sec.
SOUTHPORT. July 6th, 7th, and 8th. Mr. E. Martin, Sec.
HELMERSBURGH (ROSES). July 12th and 18th. Mr. J. Mitchell, Sec.
BRIGHTON. July 29th. Messrs. C. Jessop & E. Bawley, Hon. Secs.
REATON BURN. August 26th. Mr. R. Richardson and Mr. W. Elliott, Secs.
DUNDEE (International). September 7th, 8th, and 9th. Mr. W. E. McKelvie, 26, Euclid Crescent, Sec.

TRADE CATALOGUES RECEIVED.

Charles Turner, The Royal Nurseries, Slough.—*Catalogue of Seeds for the Kitchen Garden, Flower Garden, and the Farm.*
William Bull, King's Road, Chelsea, London, S.W.—*General Catalogue of Flower and Vegetable Seeds.*
Dick Redcliffe & Co., 129, High Holborn, London.—*Illustrated Catalogue of Seeds and Garden Requisites.*
Waite, Burnell, Huggins, & Co., 79, Southwark Street, London, S.E.—*Spring Catalogue of Flower, Vegetable, and Farm Seeds.*
James Dickson & Sons, 108, Easteate Street, and "Newton" Nurseries, Chester.—*Catalogue of Vegetable and Flower Seeds, Implements, &c.*
R. B. Matthews, 65 & 67, Victoria Street, Belfast.—*Descriptive Seed Catalogue and Cultural Guide.*
Ant. Roosen & Son, Overveen, Haarlem, Holland.—*List of Gladioli, Dahlias, Liliums, Cannas, &c.*
J. Baumann, Nouvelle-Promenade, Ghent, Belgium.—*Price Current for 1876 of Rhododendrons, Asaleas, Camellias, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

INCREASING A LAUREL'S VARIATION (D. D.).—Your Laurel bush, the one half of which is variegated, if you take a scion of the variegated part

and graft it on two or more branches of the unvariegated, would induce that to be partly variegated, but to what extent can only be known by trying.

ANALYSIS OF MILLER (J. W.).—It contains more nitrogenous matter and less starch than rice. Of mineral substances it contains about 4 per cent., and these are potash, soda, lime, magnesia, oxide of iron, phosphoric acid, sulphuric acid, sulphate of lime, chloride of sodium, and silica.

GRAFTING (T. W.).—You will have seen notes and illustrations in our last number. If you need fuller directions you will find them in our "Fruit Garden Manual," which you can have free by post for five postage stamps.

PEARS NOT RIPENING (G. C.).—It is very difficult to understand the vagaries of Pears. You would find *Buenrè* Dial ripen if the trees were planted on the wall. It succeeds on the Quince. We would advise you to gather fruit at different times, placing a label against the fruit in the room, you would then ascertain what was the best time to gather by noticing which ripened best. The beginning of December was very late. All the Pears should be gathered a month before that. If the trees you name do no better next year, head them down and re-graft with better varieties.

POTATOES FOR EXHIBITION (F. M.).—Your soil being heavy is against your having Potatoes in six varieties for exhibition in July unless you have a warm situation. The six we advise are—*Veitch's Improved Ashleaf*, *Bountiful* (Fenn), *Perfection Kidney* (Fenn), *Early Market* (Fenn), *Reactor* of Woodstock (Fenn), and *Snowflake*. Plant early, protecting from frosts.

REMOVING OIL PAINT FROM TREES (South Coast).—We presume the paint is only upon the trunks and thick branches, from which it may be removed by scraping them, than which there is no better implement than a "triangle hoe" with a short instead of a long handle, as for drilling. The scraping will not injure the trees if you do not injure or remove the layer of bark next the wood.

VEGETABLES FOR EXHIBITION (A Young Amateur).—Broad Beans—If in the pod, *Seville Long-pod*; if out of the pod, *Windos*. Scarlet Runners—*Champion*. Cabbage—*White*, *Hill's Dwarf Incomparable*; Red, *Red Dutch Savoy*, *Drumhead*. Long Carrot—*Red Surrey*. Cauliflower—*Walsherm*. Celery—*Red Leicester Red* (Major Clarke's Solid Red); *White*, *Williams's Matchless White*. Lettuce—*Cos*, *Alexandra White*; Cabbage—*Neapolitan*. Onion—*Reading* or the *Banbury*. Peas—*Longest-pod*, *Superlative* and *Supplanter*. Parsnip—*Hollow-crowned Improved*. Turnip—*Early Snowball*. Potatoes—*Kidney*, *Perfection Kidney* (Fenn); *Round*—*Early Market*, or *Reactor* of Woodstock; *American*, *Snowflake*.

CYCLEMANS IN VINEY (T. Byrne).—We do not see so far as you explain your treatment, that it is wrong in any particular, only when the Vines are started the Cyclemans from the shade and heat will be liable to be drawn-up weakly. Could you not remove the plants to a cold frame in the summer?

DRESSING VINE BORDER (F. T., Dublin).—We should prefer the half-inch bones to bone dust, giving a dressing about an inch thick, and mixing it with the surface soil as deeply as you can without injuring the roots; but as you say plenty of bones were used in the making of the border three years ago, a sprinkling of bone dust in March at the rate of 1 lb. per square yard would be an ample dressing, supplementing with a sprinkling of guano in moist weather at the time the berries are thinned, giving 2 ozs. per square yard.

MAKING A SHRUBBERY WALK (Hugh Taylor).—A curved or serpentine path through shrubs is more desirable than a straight one, and to which there is not only no objection in your case, but it is the proper form to adopt. The walk ought to have the soil taken out 8 inches deep, to have 8 inches of rough stones at bottom broken-up, and upon them may be a covering of ashes to give evenness, and then you may add the 2-inch thickness of fine gravel. The tiles should be fixed before the walk is gravelled.

LIGHTING A CONSERVATORY (Bacup).—Suspension lamps or globes having a tube from each projecting through the roof to conduct away the elements of combustion are the most suitable, and in them oil, paraffin, or gas may be burned safely. An ironmonger will procure them for you. In a notice of the conservatory at Rolleston Hall, in No. 768, some globes were referred to as answering their purpose admirably.

ROSE PERLE DES JARDINS (W. S.).—It is a good canary-yellow Rose of hardy vigorous growth. There is but one perpetual white Moss Rose, the flowers of which are neither large nor very double, but they are pure white, produced in clusters and beautifully mossed. Madame Bellenden Ker is a good white H. P. Rose.

CROCUSES FOR POTS (J. K.).—You have been correctly informed. The clumps now appearing above ground will, if potted, flower freely in your greenhouse some weeks in advance of those left in the ground.

VINCA ROSA (E. W.).—These plants may be readily raised from seed, and will flower freely the first year if grown in a brick heat, such as is afforded by a stove or cucumber frame.

TUBEROUS BIGNONIAS (J. Allen).—They are a beautiful class of summer-flowering plants of easy culture. See what is said in another part of the Journal. Cultural notes with a selection of varieties will be given next week.

HYACINTHS (Mrs. L.).—The bulbs which have pushed crowns the size of "large acorns" must be taken out of the sahes at once, and be gradually inured to the light, affording them a few days' twilight by a slight covering of moss. They may be grown-on in the frame or greenhouse, keeping the soil regularly moist. When unfolding their foliage too much light and water can scarcely be afforded them.

ALPINE PLANTS FOR POT CULTURE (Wm. Wallis).—*Aretia Vitaliana*, *Campanula garganica*, *Dodecatheon integrifolium*, *Draba glacialis*, *Epimedium pinnatum elegans*, *Eriophorum Lehenohel*, *Gentiana verna*, *Hutchinsia alpina*, *Linnaea borealis*, *Neraria depressa*, *Parnassia acarifolia*, *Pinguicula grandiflora*, *Pyrola rotundifolia*, and *Ranunculus alpestris*.

STANDARD TREES FOR SOUTH WALL (West Coast).—The most suitable trees for a south wall would be Apricots, Peaches, and Nectarines, trees of which you may obtain one or two years trained of the principal nurserymen. They will give a fair return of fruit until the dwarf-trained trees grow and require their space, when, of course, the riders should be cut away to make room for the permanent trees. You might have a Plum or two for earliness, as *Early Rivers* and *Early Transparent Gage*; and a Cherry or two, as *Early Purple Gage* and *Empress Eugénie*. Nectarines would not succeed on an east or west wall, on which Pears or Plums would be suitable. Plums would succeed against the east wall. Do not bring-up more than 2 or 3 inches of the sand, and 24 to 3 feet is deep enough to trench ground for fruit trees, less if the soil is bad at bottom. Gooseberries, if you want flavour, are *Early Green Hairy*, *Green Gage*, *Champagne*, *Yellow Champagne*, and *Warrington*

Red. It also and fair flavour:—*Red*—*Hopley's Companion*, *Guide*, and *Atlas*. *White*—*Ostrich*, *Sheba's Queen*, and *Wandering Girl*. *Green*—*Angier*, *Conquering Hero*, and *Thumper*. *Yellow*—*Marigold*, *Bank's Dublin*, and *Husbandman*. The early part of April is a good time to plant Conifers, or moist weather in late summer and early autumn. Gordon's "Pinetum" may suit you, but it does not treat of shrubs.

DAPHNE INDICA (H.).—Cut-in any irregularity of growth when the flowering is past, but not otherwise prune, and keep rather dry for a month, and yet do not allow the foliage to flag for want of moisture, then report and keep rather moist and slightly shaded during growth, and when the growth is complete afford a light airy situation. Pot sparingly, not giving a large shift, providing good drainage, and a compost of turfy peat and loam in equal parts, with a sixth of silver sand.

SYRINGING CAMELLIAS (Idem).—You may syringe the plants, but only to cleanse the foliage from dust, for if the water come in contact with the expanded blooms it will discolour the petals. We do not syringe ours more than two or three times a year, and to cleanse them of accumulated dust, but sponge the leaves twice a year—in spring before new growth is made, and in October or November, about the middle of which month they commence flowering and continue up to March. We have no blotched leaves, of which the syringing is in most instances the principal cause. Keep the roots well supplied with water, and the foliage dry.

STARTING VINES (A Constant Reader).—We should start the house the beginning of March, which will give you Grapes at the end of July and early in August, and they will hang in good condition for a long time. It will not injure the Vines to start them at that season. The Vines should have a good watering before starting, and the whole of the border brought into a thoroughly moist state. The hose-pipe should be made to pass over the whole of the border every inch of it twice at each watering, and about twice that quantity given for a yard around the stem of each. This watering will suffice until the Vines are in leaf, and then you may water every three weeks until the berries are set, and every fortnight until the Grapes are mainly coloured, when the watering should be discontinued, but an occasional watering given to prevent the Grapes shrivelling, the border being kept from cracking. Your Vines would carry a pound of Grapes per foot of rafter, or fifteen bunches of a pound each, and proportionately less as the bunches are likely to be individually heavier. Early forcing has a tendency to weaken Vines and wear them out, but it is only when forcing is going on at an unnatural season.

NAMES OF FRUITS (J. Jefferies & Son).—1, *Blenheim Pippin*; 2, Not known; 3, *Christie's Pippin*.

NAMES OF PLANTS (The Swanage Major).—Yes. It is the plant you name. (*O. B.*)—*Thysanotus Schomburgkianus* (?); 2, *Peristrophe* (*Justicia*) species; 3, *Cyrtanthera Pohlana* (*Justicia* carnosa).

POULTRY, BEE, AND PIGEON CHRONICLE.

UNSATISFACTORY POULTRY-KEEPING.

I PLACE before you the result of carefully-kept accounts of the last year's experience with respect to the keeping of fowls—I keep the *Dark Brahmas*. I have an unlimited grass-run, a good dry house with roosts 18 inches from the ground, lighted by a window which opens to the east. I have fed them thus: Morning—maize, one pint to the dozen. Noon—wheat or barley, dry in summer, boiled in winter and given hot in the same proportion, and scraps. Evening (about an hour before going to roost), wet food, sharps and ground oats in equal proportions 1½ pint to the dozen, made up into balls on January 1st, 1875. I began with twelve hens and two cocks. The result has been, to the 31st of December, 2,028 eggs. Sold 1,290; set 825; consumed 419. Hatched 186. Died 35; sold, 54; consumed 16; on hand 81 for sale. I also hatched 76 Ducks (*Aylesbury*) from 155 eggs. Lost and died 88; sold 27; consumed 8; on hand 2. I find the cost has been £28 4s. 8d. I have received for eggs and poultry sold (the fowls have weighed from 11 lbs. to 14 lbs. per couple, for which I have charged 8d. per lb. of late, and the eggs from 10d. to 1s. 8d. per dozen), taking the 81 on hand at a proportionate value, £83 14s. 4d. Now, while I am nothing out of pocket it hardly pays for the trouble. I have seen in the Journal statements of the large profits made from poultry. I may be extravagant in the keep on the one hand, with a bad market on the other, and I hope some of your readers will put me right. I perhaps might make something from exhibiting some had I the nerve. My fowls are beautifully marked—well-feathered feet (on two toes). I must relate some peculiarities which I cannot account for. One hen while sitting laid ten eggs; another killed her chicks as she hatched them, and then turned them out of the nest; another after she was loose with her brood attacked every other hen with chickens, taking them to herself until she used to go to roost with about thirty chickens. —A. P.

CORK SHOW OF POULTRY, &c.

THIS was held on the 18th and 19th inst. Nearly all the classes of poultry and Pigeons were well represented, but no bird was of such excellence as to require special notice. In the show of *Cage Birds* the entries were good, and the quality throughout better. In *Canaries* Yellow some misconception was evident, any bird not marked being considered a Yellow, and some excellent *Mealy Belgian* and *Norwich* being passed over on this account. The winners were Belgians, and such birds as would delight the hearts of some of our English fanciers to

see. In any other colour the first was a Silver Lizard, very good in all points, the spangling being about perfect; second a Buff Belgian. Bullfinches were good in colour, the Goldfinches better; but of the British birds the Linnets were by far the best, not a bad bird being shown. In Goldfinch Mules the prizes were awarded to green birds, over the heads of patchy variegated birds. There were some good dark Linnets. Blackbirds, Thrushes, and Larks were very good and well shown, showing great care and attention on the part of the exhibitor. Of Parrots there were but three; first Green and second Grey. In the Variety class a Lemon-crested Cockatoo was first, and a Virginia Nightingale second.

SPANISH.—1, S. Mowbray. 2, W. G. Henry. Dorkings, Silver-Grey. 1 and Medal, S. Mowbray. 2, Mrs. R. Sargent. Any other colour. 1, S. Mowbray. 2, J. Barlow. Huddans. 1 and Medal, Miss L. Stephens. 2, Rev. V. Holahan. Crested Cuckoo. 1, L. Stephens. 2, W. E. Forrest. Pencilled. 1, J. Barlow. 2, S. Mowbray. Pouter. 1 and 2, J. K. Miller. Game, Black or Brown Red. 1, W. Johnson, jun. 2, M. C. Cramer. Ducking. 1, J. C. Cooper. Pile or any other variety. 1, J. C. Cooper. 2, W. Johnson, jun. Any colour. Cock. 1 and Medal, C. P. Staunton. 2, J. C. Cooper. Hens or Pullets. 1 and Medal, Mrs. C. F. Staunton. 2, W. Johnson, jun. GAME BANTAMS.—1, G. Keesee. 2, J. N. R. Pim. Brahma, Dark. 1, Miss L. Stephens. 2, Mrs. Hay. Chickens. 1, W. J. Rumley. 2, A. Gwynne, jun. Light. 1, T. O. Atkinson. 2, P. Hodder. Chickens. 1 and Medal, Mrs. Forrest. 2, E. Stannell. COCHINS, Buff or Cinnamon. 1, M. Mahony. 2, Lady A. Lloyd. Any other colour. 1, L. Slaney. 2, M. Mahony. Any colour. Chickens. 1, Lady A. Lloyd. 2, Mrs. Hay. ANY OTHER VARIETY. 1, T. A. Bond (Sultana). 2, W. Hilliard (Black Bantam). TURKEYS.—1, Capt. Bury. Poults. 1, S. Mowbray. 2, Mrs. R. Sargent. GEESE.—1, S. Mowbray. 2, J. C. Cooper. Ducks.—1, F. Robertson. 2, W. H. Masey. Any other variety. 1, F. Robertson. 2, S. Mowbray. SELLING CLASS. Cock. 1, S. Mowbray (Dorking). 2, Rev. V. Holahan (Golden-spangled Hamburgh). 3, Mrs. Gibson (Black). Hens. 1, S. Mowbray. 2, Mrs. R. Sargent (Park Brahma). 3, S. Mowbray (Dorkings). 4, J. K. Miller. The Society's silver medal awarded to the winner of the greatest number of prizes in the poultry classes.—S. Mowbray.

PIGEONS.—Pouters. Cock. 1, 2, and Medal, J. H. Hutchinson. Hen. 1, J. H. Hutchinson. 2, F. W. Zurichor. CARRIERS. Cock. 1, 2, and Medal, W. A. P. Montgomery. Hen. 1 and 2, W. A. P. Montgomery. FANCIES. Cock. 1, W. J. Rumley. 2, W. A. P. Montgomery. Hen. 1, W. A. P. Montgomery. OWLS. Cock or Hen. 1, W. J. Rumley. 2, W. G. Henry. TRUMPETERS. Cock or Hen. 1, J. H. Hutchinson. 2, J. H. Perrott. JACOBIANS. Cock or Hen. 1 and 2, J. Frame. FANTAILS. Cock or Hen. 1, W. G. Henry. 2, J. H. Perrott. NUNS. Cock or Hen. 1, J. Dowling. 2, J. K. Miller. TURBOTS. Cock or Hen. 1, 2, and Medal, W. J. Rumley. MAGPIES. Cock or Hen. 1 and 2, J. H. Perrott. TUMBLES. Cock or Hen. 1, W. J. Rumley. 2, S. White. DRACOONS. Cock or Hen. 1 and 2, J. Dowling. 3, W. Johnson, jun. ANY OTHER VARIETY. 1, W. G. Henry. 2, W. J. Rumley. CARRIERS. Young. 1, W. A. P. Montgomery. BARBS. Young. 1, W. A. P. Montgomery. 2, J. Dowling. SELLING CLASSES. 1, H. L. Tivy. 2, J. Dowling. 3, J. H. Hallow. The Society's silver medal awarded to the winner of the greatest number of prizes in Pigeon classes. W. A. P. Montgomery.

CAGE BIRDS.—CANARIES, Yellow. 1 and 2, D. Ryan. Any other colour. 1, F. Brady. 2, W. Berry. BULLFINCHES. 1, G. J. W. Johnston. 2, R. Babington. GOLDFINCH MULES. 1, R. P. O'Grady. 2, W. Egan. LINNETS. 1, G. J. W. Johnston. 2, R. P. O'Grady. GOLDFINCH MULES. 1, P. Cronin. 2, Mrs. W. D. O'Connell. LARKS. 1, J. Harris. 2, R. P. O'Grady. BLACKBIRDS. 1, R. P. O'Grady. 2, G. J. W. Johnston. THRUSHES. 1, G. J. W. Johnston. 2, R. P. O'Grady. LARKS. 1, T. Babington, jun. 2, Mrs. Shee. PARROTS. 1, W. Johnson, jun. (Grey). 2, D. Morgan (New Zealand). ANY OTHER VARIETY OF CAGE BIRDS. 1, Mrs. Hodder (Lemon-crested Cockatoo). 2, R. Babington, jun. (Virginia Nightingale). The Society's silver medal awarded to the winner of the greatest number of prizes in Cage Birds.—R. P. O'Grady.

JUDGES.—Mr. E. Hutton, Pudsey.

DORCHESTER SHOW OF POULTRY, &c.

This took place on the 19th and 20th inst. The Show was an admirable one, and the arrangements in every way good. The birds had to be in the Show by 2 p.m. on the Tuesday, which was very inconvenient to many exhibitors, and we cannot see much use in the arrangement. The Judges were numerous, and performed their work well. The quality they had to adjudicate upon was decidedly above the average of many meetings of the same magnitude. When we reached the place of exhibition the cards were up and the whole building full of visitors, so we hope the undertaking will prove a success in every way.

In Coloured Dorkings the cup went to a grand old pen, good in colour and shape. The hen gave one the appearance of being certainly old, but she was very deep and massive. Silver-Greys were a nice class. We liked the cock in the third-prize pen immensely, for his colour and shape were what such a bird should be; but to judge from his comb he appeared to have come out of a fray but lately, which spoilt his chance we suppose of first honours. White Dorkings were very nice; the second only inferior to the first in size, both being good in colour and other points. Cochins were very good. In Buffs a nice pen won the cup, but we liked the first-prize pair of Partridge or the first Whites quite as well. The winning Partridges were very large and sound in colour, and deservedly took their place. In Whites the winners were well ahead; the first-prize cock being snow white, very massive, and low on the legs. The hen with him was large and abundantly feathered. Brahmans were an average collection; the Dark certainly the best. The second-prize hen was very well marked, and excellent in comb. Both the Brahma cups went to Creeping, which makes comment on their quality needless. Spanish were very good, and here the champion cup for the best pen in the Show came. They were good in every way, and the cock enormous in face; but we almost thought the champion trophy could have gone as deservedly elsewhere. But it is a long time since this breed has won a good champion cup we believe, and the wheel of Fortune should distribute her favours equally. We hear this

cock was the Bristol bird. One of his eyes looks shaky, but he is a grand bird all round. Games were admirable. The cup pen of Black Reds were very hard in feather and stylish in shape and head. The cup Brown Red cockerel was exceedingly good in tall and fine in feather. The whole team shown by Messrs. Farquharson and Volsin were very grand and really worthy of the highest credit, being in such good condition and so hard in feather. Hamburgs were a good lot, and the handsome prizes brought down the "Lancashire lads." Much as we admired the cup pen of Golden-pencils, we almost liked the second-prize pen as well in many ways, for the hen there was a gem in markings, and her tail was as well pencilled as any other portion of her body. Black Hamburgs were hardly as good as we have seen lately; we fear there is a tendency to breeding them coarse. Polands made a marvellous class. The cup went to a superb pair of Silvers; and we thought second should have gone to the same colour in preference to the Blacks, although they were an extraordinarily good pen. The cup cock was a wonder in crest and markings, and his mate as good. The whole class was a grand one, and many previous champions were here ousted from their positions. Malays were good as a class. Mr. Falle sent some nice Whites, which are rather rare, especially as they were better than usual in colour. Nearly the only pair in the class of the rich colour was Mr. Hinton's. As we have previously stated, the colour of course is simply a matter of choice, but we confess our own fancy is for the rich deep-coloured variety. In French a pen of Cives of striking blackness won the cup. They were an adult pair, but grand in all points. The Variety class was a better one than we have seen of late. The winning cards were turned up by Bredas, Andalusians, and Minorcas. Mr. Woodgate had a beautiful pen of Silkies very highly commended, their chief points of excellence being crests and leg feather. Bantams made a better display than we have seen for some time, especially in the Game, and for a wonder the cup came here instead of going to the Sebrights. The cup cock was very smart in feather and stylish in every way. The winners in Laced were good Silvers, being very clear in markings and small in size. A beautiful pen of Blacks won in the next class, and a very charming pen of Whites second.

The Duck classes were especially remarkable for the specimens of the ornamental varieties sent by Sir William Smith-Marriott. They were shown in faultless condition and feather. The first Aylesburys were very large and clear in bill. Geese and Turkeys were above the average. A very beautiful collection of Pheasants of many varieties finished up this section.

The Pigeons were a very good lot, but we were surprised and sorry to find so few entries in many of the classes. The great success of this department at Poole only a few days before seemed to make the meagre display in entries here more remarkable. The Dragons were, however, very splendid, and Mr. Bishop's brown-barred Silvers were well worthy of going to see. The cup Fantails were also a grand pair of Whites as good in tall and carriage as we have seen for some time. Antwerps were pretty fair. We noticed a strong pair of birds (659, Norwood), good in colour (Silver), but they looked too much of the stamp of the Dragon. In the Variety class, which was one of the best Pigeon classes, a very nice pen of Owls won first, being good in head and very small.

The Rev. G. Hodson awarded the prizes in Dorkings, Brahmans, Cochins, and the Waterfowl; Mr. Tegetmeier in the Polish, Variety class, Malays, French, and some of the Bantams; while we believe Mr. Hewitt took the remainder.

The cups have been forwarded to the winners and the prize-money paid.

DORKINGS.—Coloured.—Cup and 1, Henry Lingwood. 2 and 1 local, Mrs. Radclyffe. 3 and local, E. Ponting. Silver-Grey. 1, L. Wren. 2, T. Moore. 3, O. K. Greenwell. White. 1, O. K. Greenwell. 2, R. A. Botseler. 3, Mrs. Hayne. Brahma. Dark.—Cup and 1, Horace Lingwood. 2, Newham and Manby. 3, Lady Chetwynd. 1 local, R. Gower. 2 local, Mrs. Radclyffe. Light.—Cup and 1, Horace Lingwood. 2, F. D. Laurie. 3, Mrs. W. C. Drummond. COCHINS.—Cinnamon and Buff.—Cup and 1, Capt. T. S. Robin. 2, H. Tomlinson. 3, Henry Lingwood. Partridge. 1, H. Tomlinson. 2, Hon. Mrs. Sargent. 3, D. Lewis. Any other variety. 1, Rev. E. S. Woodgate. 2 and 3, W. Whitworth, jun. 1 local, J. Eper. 2 local, Mrs. Radclyffe. SPANISH.—Cup, 1, and Champion Cup, E. G. Adams. 1 local, W. E. Harris. 2 local, S. Steele. Game.—Black-breasted Red.—Cup, 1, Champion Cup, and 2, E. G. Farquharson. 2, J. Volsin. Brown-breasted Red.—Cup and 1, J. Volsin. 2 and 3 local, E. G. Farquharson. 3, H. Browne. Any other variety. 1, E. G. Farquharson. 2, J. Volsin. 3, H. Browne. HAMBURGERS.—Gold and Silver-pencilled.—Cup and 1, W. K. Tinker. 2, H. Beldon. 3, H. H. Thompson. Golden-spangled.—1, H. Beldon. 2, F. E. Jones. 3, S. H. Harris. 1 local, W. Meader. Silver-Grey.—1, W. Adams. 2 local, Mrs. E. Farquharson. Brown-breasted Red.—1 and 2, S. Beighton. 3, W. M. Cardell. Any other variety. 1.—Baker. 2, F. S. Hockaday. 3, S. Beighton. 1 local, H. S. Handford. Gold and Silver-laced.—1, C. H. Foote. 2 and 3, M. Leno. Any other variety. 1, W. H. Shackleton. 2, H. Beldon. 3, T. Bush. SELLING CLASS.—Dorkings, Brahmans, or Cochins.—1, H. Tomlinson; 2, Whitehead. 3, F. D. Laurie; H. Johnson. 4, Mrs. Hayne; 5, Teescher. Any other variety.—1, H. Yardley; 2, Bush. 3, E. G. Farquharson; 4, Rev. E. Handley. 5, M. Sturt; 6, T. Jont. Ducks.—Aylesbury.—1, J. K. Fowler. 2, S. H. Harris. 3 and 1 local, Mrs. Martin. 1 local, Mrs. Radclyffe. Rouen.—1, J. K. Fowler. 2, T. Moore. 3, J. H. Holt.

1 local, E. Ponting. 2 local, Mrs. Radclyffe. *Black East Indian*.—Cup and 1, S. Bura. 2 and 3, J. W. Kelleway. *Any other variety*.—Cup, 1, 8, and 1 local and Cup, Sir W. Marriott, Bart. 2 and 2 local, C. H. Mayo. *Selling Class*.—1, H. Feast. 2, T. Moore. 3, J. Hodges. *TEA-SHAWA*.—1, Rev. N. J. Riley. 2 and 1 local, E. Ponting. 3 and 2 local, Mrs. Radclyffe. *GENAS*.—1 and 1 local, Mrs. Radclyffe. 2 and 2 local, E. Ponting. 3, J. K. Fowler.

PURASANTS AND PRINCESS.—*Phaenax*.—1, Sir W. Marriott, Bart. 2, Mrs. W. C. Drummond. 3, W. O. Drummond. *Carriers*.—Cup and 1, H. Yardley; 3, A. Heath; H. Jacob. 1 local, H. S. Hansford. *Poulters*.—Cup and 1, H. Pratt. 2, A. Heath. *Hens*.—1 and 2, H. Pratt. *Tumbler*.—Cup, 1, and 3, H. Yardley. *Barbs*.—1, H. Yardley. 2, P. H. Jones. 2 local, C. Parsons. *Turbit*.—1, C. A. Grafer. 2, P. H. Jones. 3 local, C. Parsons. *Jacobins*.—1 and 3, J. Andrews. 1 local, C. Parsons. *Swiss*.—1, Miss A. Brooks. 2 and 2 local, C. Parsons. *Anticorns*.—1, J. J. Bradley. 2, G. Colson. *Dragons, Silver*.—1, 3, and 1 local Cup, W. Bishop. 3 local, W. Oswald. *Blue*.—Cup and 1, E. Woods. 2, W. Bishop. *Red or Yellow*.—1 and 2, E. Woods. *White*.—1, 2, and 1 local Cup, W. Bishop. *Any other distinct variety and local*.—1, F. Braund (Owls). 3, H. Yardley. 1 local, Mrs. C. Parsons (Joc). 2 local, G. C. Farrer (Fribbles). *Selling Class*.—1, Mrs. W. C. Drummond. 2, W. E. Rootes. 3, C. Parsons.

THE WONDERS OF A BEE HIVE.—No. 8.

THE first fortnight of the life of a queen bee is very eventful, often very tragical and calamitous. More queens are hatched than the exigencies of hives require. The supernumeraries are destroyed either in royal battles or by the community before they are many days old. Even after all the supernumerary queens have been killed and the rest enthroned, every one in its own hive, young queens are exposed to danger during the honeymoon season of their lives, which happens before they are fourteen days old. Many queens never return from their first tours. Some of them may be drowned in ponds and rivers, some caught by birds, some miss their way home. We cannot tell how they are lost. Much of their life indoors is surrounded by mysteries which man cannot penetrate, and his eye cannot follow them over fields and forests outside.

All queens that have been successful in their outdoor excursions have the maternal duties of their hives to perform. The office of a queen is no sinecure. What common working bee is so heavily taxed with toil? What life so laborious, monotonous, and exhausting as that of a queen bee? Where can a life be found more exemplary for patience and perseverance? Four years of heavy work unflinchingly met! No holiday—no pleasure excursion for a queen bee! No day of rest does she ever seek! And who dares affirm that she ever has one hour of sleep?

Queens commence laying when they are about ten days old, generally speaking, and continue to lay during the summer months till the time of their decease—viz., when they are four years old. A few die when they are three years old. Their fertility is one of the wonders of bee history. We are not aware that it has been accurately ascertained how many eggs a queen lays every day. So far as my own experience goes it leads me to put the number beyond 2000 daily. Langstroth put it between 2000 and 3000 daily. Some experiments made in America indicate that our estimate or guess is much under the number. One writer informs us that through a glass hive he saw a queen laying eggs at "the rate of six a minute." If she kept on at this rate 5000 would be laid in twenty-four hours. Even 2000 eggs laid daily for months by one queen seem a marvellously large number. The prolific character of queen bees has not been sufficiently pondered by many apiarists, otherwise their hives would have been constructed much larger. More than half the eggs laid by queens are destroyed for want of room to set and hatch them in the present race of hives.

Have queens the powers to repress egg-laying? Can they lay and cease to lay when they like? I have never seen any evidence indicating that they could lay or cease to lay when they like, or even to lay according to the wants of their hives. Dr. Bevan was wrong in stating that queens have two great seasons of egg-laying—viz., one before swarming and another after swarming. He fancied that queens stopped laying before swarming and recommenced afterwards. That is erroneous, for queens continue to lay up till the moment of swarming, and they will lay eggs on the flight board in the act of swarming. If a first swarm be hived amongst empty combs we invariably find that the combs are speedily filled with eggs. There is no cessation of egg-laying at the swarming season. One of the easiest ways of finding how many eggs a queen bee lays is to put a first swarm into a hive of empty combs for thirty-six hours and then count the eggs laid during that time. In seasons of inclement weather there sometimes seems to be a cessation of egg-laying. No eggs are set—the combs become empty. This is a very common occurrence, and has led some honest men to think and say that the queens have become barren for a time. I have not been able to endorse this opinion, for I find that in hives with plenty of honey in them egg-laying is seldom discontinued during the multiplying seasons.

In hives on the borderland of starvation during inclement weather we find that eggs are not set, and often much of the brood that is half-hatched is torn from the cells and cast out of the hive. The bees anticipate a famine and wisely cast out their young. The instinct that causes them to cast out their young may teach them to destroy eggs, and thus save them-

selves from the burdens of an accumulation of brood. I do not say that cold inclement weather does not influence the productive powers of queen bees, as it certainly does in the case of fowls; but I have not found material enough in the evidence adduced by some writers on this question to convince me that queen bees have ceased to lay when eggs are not set.

How the queens or bees know male from female eggs is a wonder to many. Male eggs are laid or set in drone cells, and female eggs in worker cells. Can a queen bee, by a mere act of her own will, determine gender before the egg is laid? If not, how comes it to pass that each kind of eggs are placed in appropriate cells? If the queen cannot determine and destine the sex of the eggs, which "great bee" knows the difference between male and female eggs, and separates the one from the other after they are produced? Such questions lead us into a wilderness of thickets, and leave us to find our way out as best we can.

After the first fortnight of her life a queen bee discharges the duties of maternity. The drain on her strength by such maternal functions must be very great. Some one has said that a queen is an enormous eater. No one will dispute this. Constant feeding and generous food are necessary to keep her at work. Strange that a bee of fragile build should lay so long and well. "You must admit that a queen bee has one airing and holiday once a year—when the bees swarm." Yes, she does go with the swarm; but it cannot be called a holiday or pleasure excursion. She is a creature of circumstance then and follows the majority.

One of the wonders of a bee hive is the fact that the inability of a queen to fly far is taken into consideration by the community before they emigrate. Old and pregnant queens go with first swarms, which settle or alight on branches near home. First swarms seldom go many yards from the old stands. Second swarms or casts have young unfertilised queens, and these often go farther from home. First swarms with old queens are afraid to depart if the weather be at all threatening; second swarms are less particular about the weather or the hours of swarming.

Though the queen leads a life of drudgery and monotony she leads it most contentedly amid an affectionate and admiring people, who study her every want and remove every pebble out of her pathway. She is the highest personage in the realm and receives the greatest homage. Disloyalty finds no place within the sphere of a bee hive. A queen lives to see generations of her own progeny come and go. The time of her dotage arrives—the doctor sees that her end is nigh—a gentle push will put her aside, for she staggers in her gait. The bees, knowing all this, make preparations for her dethronement by rearing young queens, one of which must be chosen as her successor.—A. PARTISHEW.

EKES VERSUS SUPERS.

A QUESTION from a correspondent on the subject of ekes, which has been forwarded to me by special request of the writer, gives occasion for a few remarks on the subject generally. I am the more induced to write upon this question because I have written on both sides during the last year or two in the pages of this journal, and I may be charged with uttering an "uncertain sound," than which nothing can be more disastrous either in regard to religious doctrines or (to pass by a bound to the humbler region of) bee economies.

Latterly I have said a good deal touching supers, and your readers are in no doubt as to my opinion of the superiority of these, in point of profitable management, to the old-fashioned use of ekes. But this depends a good deal upon the relative nature of quantity *versus* quality in the production of honey. If you want a great quantity of honey and are not particular as to its coarseness, and if you aim at honey in the jar rather than honey in the comb, then no doubt a judicious use of the eke system of space-enlargement will be your best policy, and the plan suggested by your correspondent "F. J." will be found very practicable. We should agree with him entirely if, instead of saying that working bees with ekes is the best plan of "making money," he would write of "making honey;" for I believe that at least a third of the quantity made by the use of ekes if collected in supers would make more money. His plan is as follows: He would use plain wooden boxes, not bar-frames, "16 inches square and 4½ inches deep." I should prefer at least 6 inches for the main box. "F. J." continues, "When you have a swarm in one of these put an eke to it, which will make the stock box then 9 inches deep. As soon as they have this full and want room add another eke same size, and if the season allows them to fill this add another. Supposing this to be done, the hive would be 18 inches deep. Each division should have an adjusting board between, so as to keep the combs separate in each." At the end of the season he proposes "to drive the bees down to the bottom of the hive with a puff of smoke," after removing the top board of all on the uppermost box, "and taking off the top box or two, which can easily be separated without breaking the combs;" a loose top could then be screwed on

at once before the bees have time to ascend, and at the end of the season, or earlier if the bees have not a sufficient store of honey, they could be "fed up to it." This is no doubt a very excellent plan, nor can we see why it should fail in its object, that object being a large quantity of honey. Some of it no doubt would be of first-rate quality, because it would be stored in a new hive by a swarm of the current year.

I would merely suggest that guide combs should be affixed to the upper part of the boxes in each case, so as to induce the bees to work their combs throughout from top to bottom in the same direction; also narrow apertures 6 or more inches long and half an inch wide should be made to run between the combs at the sides (not in the centre, however) to render as easy as possible the access of the bees to every part of the hive. If your correspondent carries out his plan of management as detailed here in the coming summer, we shall all be very glad to hear of the result. He may find some detail capable of improvement in the course of his practical experience. We should expect a large harvest of honey of various quality, but we think that the following year it would be better to vary his management by the use of supers over the surviving stock hive, as it would no longer be what it was the first year—namely, a swarm in a new box with perfectly fresh honeycomb. The plan seems eminently suited to swarms of the first year.

It will have been observed that I suggest the narrow passage communicating from box to box to be at the sides and not at the centre of each; this is with a view to economise and concentrate the heat necessary for the brood at the centre of each box, and to check as much as possible the ascent of the queen to the upper boxes after she has once descended to a lower region. This will tend to the greater use of the upper boxes for honey, and to its greater purity.—B. & W.

OUR LETTER BOX.

BLACK HAMBURGERS (Bosco).—The Black Hamburgs are as good layers as the others. We cannot tell you who is the best person to apply to. We advise you to look in our advertising columns. You will find all the best yards represented there.

HENS DYING (Raven).—Your feeding is at fault. You must discontinue potatoes and Indian meal. The former always cause diseased liver, and the latter makes fat only. Procure some ground oats or barley meal, slake them with water, or milk if you have it, and feed with it morning and evening. The mid-day meal may be whole barley, and after the fowls are restored to health you may give Indian corn whole three days per week. We have never been able to make our fowls eat Indian meal.

PULLET'S LEGS USELESS (A Subscriber).—We are disposed to think your pullet is egg-bound. That has the effect of causing apparent paralysis. The cure is to enable her to lay the egg. Pullets only are subject to this malady, and only with the first two or three eggs. The cure is to pull out a soft wing or a tail feather, to dip it in oil, and to pass it down the egg passage till it meets the egg. It will be laid immediately. You must not attempt to help its passage with the fingers, lest you break it in the pullet. That is a very serious case.

ARTIFICIAL MOTHER (W. W.).—The Americans use a piece of sheep-skin nailed on a board woody side upwards, and the board supported so far from the floor that the chickens can creep under and have their backs among the wool.

PAINEY POULTRY SHOW.—Mr. Sample of East Kilbride informs us he obtained the special prize in the Braham class.

AGES OF EGGS FOR SITTING (Agnes).—We prefer eggs not older than a fortnight. Eggs much older have produced thrifty chickens, but it is certain as a general rule that the older the egg the weaker its progeny. To keep the eggs until you are ready for them put a box in a dry place in your kitchen, not too near the fire; partition the box, so as to hold separately the different eggs of the various sorts; let bran be well dried in the oven and put into the partitions, and cover the eggs with the bran as they are placed in; and this should be done soon after they are laid.

AN AFFLICTED PARROT (J. T., Isle of Wight).—The symptoms so fully described in your letter are sufficiently conclusive as to the state of your Grey Parrot. The peculiar twisting of its head and neck, the film over the eyes, and the plucking of the feathers, will most likely be followed by occasional falls from the perch and violent fits. When the latter occurs supply it with a few drops of weak brandy and water. The Parrot is suffering from vertigo (an affection of the brain), which is so connected with the vertebra of the neck as to bring about the painful-looking contortions of the neck in particular. We have ourselves lost Parrots in this way, and likewise know of numerous other instances of deaths occurring. The complaint is attended with difficulty of swallowing and occasional vomiting. Your general treatment of the bird we cannot complain of, excepting that Parrots should be sparingly supplied with flesh meat, especially when in a raw state. All that you can now do is to give the bird a tepid shower bath every other day, after which dry the bird's feathers gradually before a fire. Administer three or four drops of castor oil twice a week, which will tend to check the offensive smell you complain of. Keep the bird upon a soft diet (which will be easier for its throat), such as bread-and-milk and Indian corn well scalded and soaked in milk. Discontinue flesh meat and hempseed. This treatment will only tend to prolong its suffering life. With such a faint hope of recovery it would be humane to terminate its misery.

DRIVING BEES (J. B.).—To drive bees from common hives when they are to be preserved and the honey and combs taken. Early in autumn, or say in the month of August, blow some smoke from old corduroy or cotton rags amongst them, turning the hive upside down or flat on its crown, placing an empty hive about the same size on and over it mouth to mouth, and rolling a cloth of any kind round the junction to keep the bees from escaping or coming out. The drumming or driving now begins by beating the sides of the hive with both hands. This beating on their hive while they are confined confounds them and causes them to run from the bottom hive as fast as

they can. They are completely mastered and cowed; and in a panic-stricken condition they abandon their brood and everything cared for before, and seek safety in flight. About fifteen or twenty minutes of drumming drives all aloft. There is no time allowed for rest or play after the beating begins. From beginning to end the drumming should be continued, not giving the bees time to think or turn round. And when the bees are up they should be lifted off the old hive and placed on its board. All this may be done in a hive of any size or strength in less than twenty minutes. If a few stragglers are left in the bottom hive they may be driven out with a feather. As it is very important to run the honey before the combs cool we generally destroy the stragglers speedily with a puff of powder or a small bit of brimstoned-rag. We like to have all the honey run from the combs by the end of an hour from the time we commence to drive. As "object lessons" more speedily convey information and impress the mind than the A B C of teaching, I often wish that the bee-keepers of England were by my side for a week to witness how easily and speedily everything is done. If "J. B." and others will only take the above A B C lesson and make it into an object lesson in their own garden or apiary they will require no more teaching on this subject. In cold weather bees do not run so readily as in warm weather. When bees have to be driven in cold weather we find that by sprinkling them with syrup fifteen minutes before the driving begins they run very well.—A. PATTISON.

Price (H. C. E.).—The most useful book is "Domestic Pigs," by H. D. Richardson.

REMARKS.

19th.—Dull morning; fine two or three hours in the middle of the day; but rain before 5 P.M., and cold at night.
20th.—Gray and rather windy in morning; fair but not bright in the middle of the day; no sun, but the pavement drying-up towards night.
21st.—Dull, slight rain at 9 A.M., and more or less all day; heavily at night, with high wind and hail.
22nd.—Wind went down about 8 A.M.; very fine at nine, cloudy for a short time about 1 P.M.; but on the whole a fine bright day.
23rd.—Very fine all day, and a starlit night.
24th.—Fine morning, rather less so about 1 P.M., but a fine afternoon and evening.
25th.—Very dense fog in the morning, continuing all day; the sun endeavoured to shine through it in the middle of the day for a short time, but it came on again very soon.

No especial feature during the week. The heavy snowstorm which occurred in the midland counties being merely represented here by a sharp hailstorm about 11 P.M. on Friday.—G. J. SYMONS.

COVENT GARDEN MARKET.—JANUARY 26.

A BETTER tone has pervaded the market the last few days, and best goods are readily cleared at last week's prices. Large quantities of St. Michael Pines are still arriving in good condition, as many as seven hundred having been sold last Friday alone.

From observations taken near London during forty-three years, the average day temperature of the week is 45.7°; and its night temperature 32.2°.

THE FORMATION OF A CARRIAGE OR OTHER ROAD.

UCH as we are indebted to our early ancestors for the very substantial way in which they formed their roads—roads which even to the present day seem to bid fair to witness the decay of others that are many centuries their juniors—there was nevertheless something in old Roman roads which would not have met the requirements of the present generation. Still we may wonder that the Romans were able to accomplish so much as was done, their massive walls and solid buildings, as well as their most substantial causeways, crossing the country in various directions; but then it must be remembered that all travelling was done in those days without the aid of wheel carriages. Horses, bullocks, and foot travelling were the modes adopted at that time, but with the advance of wealth other modes of travelling were required, and roads of a kind on which wheel carriages could be used at all seasons had to be provided. Coeval with this improved state of road-making it was discovered that curving round the base of a hill was not any longer than going right over the top of it; for notwithstanding the assumed theory that the up-and-down-hill road is the straightest, it is in reality no straighter than the curved one. In practice a considerable space is often sacrificed, and as it frequently happens for a gardener to have to set out a road through very difficult ground, a few plain hints may perhaps be of some service to those who have not had much experience in such work.

Assuming that a carriage road is wanted to unite the mansion with the principal highway, the route being through a dense coppice. The ground is very uneven, perhaps, along the side of a river or stream, and with now and then very steep banks. On a place of this kind considerable excavations will be required, but some judgment will often lessen this by the designer of the road making himself thoroughly acquainted with the whole of the ground before a spade or axe is put to use. The ground should be gone through several times, and if the bed of the stream be handy it forms a very good guide, and a rough idea of the ascents and descents to be made will be thus obtained without the aid of any instruments whatever. Instruments are very useful, but the plain man can very often do very well without them, the eye enabling him to judge of the difficulties in the case, and to balance the ultimate result with the labour entailed. While the work is in hand let it be well done—that is, let a proper foundation be made, with gradients of a kind that are not likely to be found fault with hereafter, for the complaint—"that it is a pity that such and such an excavation or embankment was not made at first"—ought never to be heard; for be it observed that a road of the kind in question ought to be done for perpetuity; and where there is a necessity for excavation, which in all hilly ground is sure to be the case, it is much

better not to begrudge the cart or wheelbarrow work at first, as it cannot well be done afterwards.

In the formation of a road along the side of a steep hill, with irregular gullies crossing its course, a greater or less amount of excavation of the one side and embankment on the other is indispensable. Care, however, ought to be taken at the beginning that the proper level, if we may call it so, is started with. More than three-fourths of those not having had experience in such work start too deep, or in other words, they do not give sufficient credit to the filling-up qualities of the material they excavate, the result being that they find they have more than they have room for. This arises from not remembering that a cubic yard of solid excavation does the filling-up of quite 1½ yard of embankment; consequently the material is not all wanted that ought to be removed. Some little measurement will obviate this; but many experienced people disregard such measurements, and judge by the eye how much filling-in a certain cavity will take, and how far an excavation of a certain depth will go towards that object. Of course everyone knows that there is a sinking of embankments, and what takes place during the time the works are in hand must be made up; heavy rains and carting will tend to consolidate the mass. Where bridges are needed they ought of course to be erected before the groundwork approaches them. In order to ascertain the gradients some rough survey ought to be made and levels taken. If, for example, the ascent be 120 feet in half a mile, a very little knowledge of figures shows that if excavation could be carried carefully out from end to end there would be an inclined plane of an easy rise of 1 foot in 22. A gentle and easy rise, no doubt, but it is not always easy to excavate the ground so as to have such a uniform rise, as very often the conformation of the ground almost compels a part of the road to be much steeper and a portion even level or with little rise at all. This state of things must be met as it best can, taking care in all cases after once commencing the ascent not to descend again if possible. Although there are plenty of roads that ascend the hill with a rise of 1 in 15, and some as steep as 1 in 12, it is better to spread the ascent into more space if possible; 1 in 18 being fair trotting ground that may be taken as a guide.

Now, in carrying a road through a coppice it is good practice to cut with a spade a series of small level spaces all along the intended line of route at about 50 yards from each other, or further apart if they can be seen readily; an engineer's level will then enable the respective heights of each to be ascertained. The whole should be committed to paper so as to give the profile of the ground, and the places where it is prudent to excavate and where to be filled up will show themselves at once. In levelling, a knowledge of geometry is no doubt valuable, but there are plenty of cases where such instruments as spirit levels are not cared for, the sole guide being the eye, aided by the judgment necessary to grasp quantity, and, as a friend once expressed it, see into mountains.

Where the excavation is a deep one and the cuts through a sort of a ridge, it is better to begin at both sides, taking

a rough level at the top, and ascertaining how deep the cutting will be at that place, and giving instructions where to begin at the sides, making sure not to cut-in too deep, or ten to one but the material will be more than sufficient to fill up the embankment. The sloping sides of the cutting will also require some judgment in forming. Hard dry substances like chalk or stone are sometimes cut as steep as to show a face at an angle of 60°, while a running sand or wet clay will not stand at more than 25°. The bank is generally expected to be clothed with something or other, Ivy not being at all unsuitable.

But however steep the cutting may be the embankment cannot be made steeper than about 1 in 85 or so, which is about a rise of 2 feet on a base of 8. Loose material will not hold together much steeper than this. Another thing to be considered here is the intended width of the road. A carriage road ought not to be less than 12 feet wide of stones, with at least 8 feet on each side of level sidings; if more, so much the better, the above being taken as the minimum. Moreover, for a road carried along the side of a hill provision must be made for carrying off the water, and a drain along the base of the cut-in side and one in the centre will be found useful. Embankments rarely require draining—i.e., if both sides are above the surrounding ground, but of course outlets for all surplus water created by thunderstorms ought to be thought of before the stones are put on.

I ought to remark that all curves should be of a bold and agreeable nature, avoiding undue twists and turns. Where the eye can command a distance the curve ought always to be in one direction, unless there be some interruption in the way as a pond, or tree, or other object, for nothing looks worse than a turning where there seemed no difficulty in making the road straight.

Details for applying material for roads to the best advantage may fittingly form the subject of a future communication.—J. ROBSON.

SOIL FOR RHODODENDRONS.

THE antiquated notion that peat soil is a *sine quâ non* to insure success in Rhododendron culture is now pretty well exploded, and Rhododendrons are now planted in ordinary soil with other shrubs without any special treatment or preparation with perfect confidence of success, provided the soil contains no lime. Since this fact became established it has led to that extensive use of this finest of evergreen shrubs so much to be desired, but which formerly was regarded as a luxury only to be enjoyed by a favoured few.

During the past four or five years I have planted many thousands of Rhododendrons, including varieties ranging from the pretty little dwarf alpine species upwards to the towering hybrid majesties, without having to record a single instance of failure or sickly growth. Success so perfect and full as this is of course very gratifying, yet no special merit can be claimed on the score of high culture or careful tending. The planting was well and carefully done, and the rest was left to Nature. With few exceptions the soil and situation of the various clumps and masses are the reverse of what might fairly be termed favourable—on the sides of steep slopes and banks, in a cold low-lying bog, upon a high open plateau that is often swept by violent storms from the south-west, along the sides of wood paths among a wild tangled undergrowth, under the shade and drip of trees and by the margin of water, in deep natural beds of peat, in poor thin loam, or in soil that is literally rusty with an ochreous deposit from the percolating water of mineral springs, and in marl of such a close heavy texture that but few other shrubs will grow in it at all.

Under all these conditions do Rhododendrons flourish in perfect health. The growth is most bushy, short-jointed, and compact in the peat; it is also very bushy in the thin loam; in the marl it is absolutely rampant. Let me give an example: About four years ago a quantity of soil was excavated for the foundations of a building and thrown into a long ridge 10 feet high to conceal a drying ground; most of it was a white marl, cold, sodden, heavy, and inert, and I was somewhat at a loss what to clothe it with; among other plants I resolved to try a few dozens of Rhododendron ponticum, which, to my surprise, quickly became established, appearing absolutely to revel in a medium one would have thought likely to prove fatal to the fine thread-like roots, which evidently partake more of the toughness of wire than the softness of thread. They sustained no check and exhibited an annual increase of vigour, many of

last year's shoots being from 1 to 2 feet in length, quite an inch in circumference, and clothed with foliage of proportionate size and strength. Having lately had occasion to remove some of them I found the marl clods full of roots, yet the plants did not lift with very compact balls, but rather with several clods bound together by the roots, but retaining very much the same form which they had when thrown together four years ago, thus clearly demonstrating the tenacious nature of the marl.

Rhododendron ferrugineum forms an admirable fringe to a fountain on the sides of a cascade. I have used a third of broken brick and stone in the soil for this variety, so as to let the moisture caused by the constant dash of spray among the foliage to pass from the roots quickly and find it to answer admirably, the growth being dense with healthy foliage, and the plants quickly merging into a compact belt.

Under the shade of trees the growth of Rhododendrons is apt to become thin and long, but it is never slender, the shoots being as robust as those of a common Laurel. Thus, then, in the Rhododendron we have a shrub which neither drip, shade, exposure, or poverty of soil can affect; a perfect weed in hardiness, adaptability, and tenacity of life, and yet a perfect gem—a queen among shrubs—its rich foliage and richer flowers causing it to be regarded as the "glory of spring and early summer."—EDWARD LUCKHURST.

MASDEVALLIA DAVISII.

THIS plant in your report of the Floral Committee is stated to be one of the Chelsea seedlings—[a clerical error; it should have been introductions]. Some other plant must have been intended, for no seedling Masdevallias have yet flowered in England. The plant exhibited by Mr. Burnley Hume was, as you state, in splendid health, the flowers being both beautiful and distinct. M. Davisii was introduced by the Messrs. Veitch of Chelsea from the Peruvian Andes through their collector Mr. Davis. It is not such a fine species as M. Veitchii, but the clear orange-yellow flowers have a fine effect amongst other plants in the cool house.

It is also stated in your report that the plant had a first-class certificate on a previous occasion. I am not sure whether this is correct; if not, it certainly ought to be certificated. As exhibited it was well worthy of that honour. The plant has not been long enough established in this country to have attained perfection, and January is not the best month for this class of flowers opening. I think it a first-class plant, and far superior to many Masdevallias that have been foisted on the growers of this country through foreign agency and at a far higher price.—J. DOUGLAS.

[It was certificated on August 18th, 1875.]

APHELANDRA AURANTIACA BOEHLII.

"R. H. S." is rightly "informed by a gardener that the most easy and certain way of raising a stock of this stove plant is by sowing the seed in heat in spring, &c.," as was pointed out in our Journal, vol. xxiii., new series, page 72.

In our stove this plant has been for some years almost a weed. We have several dozen plants in 4-inch pots seedlings of about 6 inches in height without the flowers, and from autumn to spring they enliven the house with their noble spikes (as many as the plants have crowns) of the brightest orange scarlet. I have seedlings which have flowered twice or thrice, some four times, and they are not more than 6 to 8 inches in height. These plants flower at almost all seasons of the year, the plants being in various stages; and the flower spikes as they go out of bloom being removed, from the axils of the leaves next below will appear two shoots, and these, if the roots are cramped, will not elongate more than an inch or two, having prominent apices from which will appear in due course spikes of bloom.

I am glad "R. H. S." has drawn attention to the easy culture and highly ornamental character of this very useful plant, which succeeds in a cool stove or warm greenhouse.—G. A.

THE ARRANGEMENTS OF COLOURS

IN THE BEDS OF THE LONDON PARKS AND GARDENS.—No. 4.
DESIGNS FOR FLOWER AND CARPET BEDDING ON GRASS.

As green is the predominating colour in Nature, enlivening, subduing, and refreshing, we must have it for a groundwork

in all our arrangements. Ofttimes more of the beauty of a garden depends upon the healthy hues of the shrubs and the verdure of the lawn than on the flowers. If bright colours preponderate they oppress, but if associated with an ample green setting they cheer and satisfy the eye and mind. The art of the florist and gardener, as far as colours are concerned, consists in arranging plants so as to produce harmony of form and colour in both foliage and flowers, as in flower-garden groups, beds, belts, ribbons, and conservatory arrangements. It is to aid those who are not skilled in the arrangements of colours that a few examples are submitted at a period when preparations are being made for the ensuing summer's display. Ladies of late years have aided in the arrangements of colours in their flower gardens, and we must admit they have displayed considerable taste; but in order that their plans may be effectively carried out it is imperative that they be submitted to the gardener some months prior to the bedding-out season. Delay in this matter is a common source of failure, for however skilful a man may be, he cannot prepare the plants when time is not afforded them to grow. On pages 488 and 489, vol. xxviii., suitable modes of planting beds of a circular form, numbered A and B, were submitted, and I now continue the series.

BED C.

1. *Leucophyton* Browni.—This is undoubtedly one of the very finest plants for carpet bedding or any select design. In flower beds it cannot fail to become a universal favourite. Its compact upright habit, and its numerous branches of small white shoots standing up as stiff as wire, which makes it so useful for panelwork and forming divisional lines. This plant has been kindly treated, and yet treated wrongly. It has been put in a warm house, which has made it look sickly; it dislikes even the smell of the fire. The proper place for it in winter is a cold frame; it will live and be healthy the whole time. It will strike very readily in a cold frame, and that is the only way to ensure its success.

2. *Coleus Verschaffeltii splendens*.—This is a very beautiful

variety; it is a sport from *C. Verschaffeltii*. The colour of the leaf is much brighter, the habit dwarfer, which makes it an improvement for decorative purposes. It is a gem among the *Coleuses* distinct and beautiful.

3. *Alternanthera magnifica*.

4. *Lobelia Porcelain Brilliant*.—This beautiful variety is a valuable addition; it produces a profusion of fine expanded light porcelain blue flowers, prettily relieved by a small white eye. It is a tone of colour very effective in contrasts for the decoration of the flower garden.

5. *Golden Pyrethrum*.

6. *Alternanthera versicolor*, mottled rose and carmine. This is a very distinct and pretty variety, splendid in colour, dwarf and compact in habit, and admirably adapted for the decoration of beds in an exposed situation. It must not be planted in too rich soil, or it is apt to grow too strong and become green.

7. *Sedum acre elegans*.

BED D.

1. *Perilla nankinensis*.—The entire plant is of a deep bronze purple colour, almost black, crisp and curly. It contrasts best with yellow. It is an annual. Sow the seed in March.

2. *Golden Pyrethrum*.

3. *White Lobelia nivea*.—I consider this the best of all the white *Lobelias* both in purity and size of flower.

4. *Coleus Verschaffeltii splendens*.

5. *Verbena Sportsman*.—A rosy pink colour. It originated in Hyde Park, being a sport from *Purple King*, and is in every respect the same as *Purple King* except the colour. It is a pleasing acquisition. No less than ten thousand plants were used in the above park during one season, and which won general admiration.

6. *Lobelia Masarine Gem*.—New, an admirable variety. It is quite unequalled in depth and brilliancy of colour, and produces its blooms up to the very end of the season.

7. *Alternanthera amena*. Brilliant magenta red.

8. *Echeveria secunda glauca*.—N. COLE, Kensington.

MESSRS. STUART & MEIN'S PROLIFEROUS SCOTCH KALE.—At first sight or seen from a distance this looks like a good stock

Fig. 22.—Bed C

Fig. 23.—Bed D

of Kale, or "Curly Greens," as the vegetable is designated by the country folks in Scotland. On a nearer inspection the whole upper surfaces of the leaves are thickly studded with beautifully curled secondary growths or leaflets; they grow so thickly on the ribs of the leaves as to conceal them quite when the plant is growing. I had one of the "Greens" cooked, and it proved to be of most excellent quality. As far as I am aware this is a distinct vegetable, and as it was shown at South Kensington well worthy of culture.—J. DOUGLAS.

WAR WITH INSECTS.

It is very fortunate for gardeners that the treatment best calculated to grow plants vigorously and healthy is also that most distasteful to insect life. Let a cold draught or a dry heat cripple the tender newly grown foliage, and red spider, thrips, and aphids are delighted; they increase and multiply by myriads. On the other hand a sturdy dark green foliage will generally be shunned by them; there is, then, a double reason for keeping plants in a fresh thriving condition. The amount of injury done by insects is not sufficiently taken into account, and it is, perhaps, more because they are loathsome to the sight than for anything else that they are looked after as well as they are. But I am persuaded that there is hardly a plant grown which, if it receives a severe check from insects or otherwise, can quite recover from it. It will, like a patched-up member of the animal kingdom, have a weak point somewhere in its constitution, where it will be more susceptible to injury than others which have not received such a check.

There is very little apparent difference between the treatment given by a successful and an unsuccessful grower. The principal difference consists in the former paying attention to very small details which the latter thinks useless and contemptible. What if a plant should droop a little, or have an insect or two hid away in its foliage? It is of no great consequence to the one, while the other would almost as soon see his plants dead as that such a thing should happen. Success is always gained by strict attention to very small matters. I will endeavour to point out a few of them which I think merit more attention than they usually receive, and which if attended to would materially lessen the labour employed in cleaning plants.

I will pass over the question of high night temperature kept by artificial means, as I have reason to believe that is nearly a thing of the past. But what about giving air in the morning? Is it never given too late or too abundantly? Imagine a house with a temperature of 70° while the air outside is frosty. Fill the house with tobacco smoke and watch how very rapidly it all escapes through the smallest apertures. The air, I imagine, of the house changes in nearly as short a time as it takes the smoke to escape, and of course would change just as rapidly if there were no smoke there, the smoke only making the movement of the air visible. The greater the difference between internal and external temperatures the more rapidly will the air change in the house, and therefore the openings for ventilation ought to be regulated according to such difference. People are too much afraid of letting the sun help them to do their forcing; they neutralise its good effects by letting in a rush of cold air. We are getting better in this respect, but there is still room for much improvement. There must be more nature-forcing; the more light the more heat and moisture should there be. Many people would be surprised at the amount of heat some plants will flourish in when they have sufficient sunlight and moisture, if they have not previously been drawn out too much with fire heat during dull weather.

I have at times been much abused for recommending low figures for night temperatures, such as 55° for Cucumbers, Muscat Grapes, &c., and perhaps some people have even been inclined to doubt my statements because they themselves have not succeeded under such conditions. The fact is my mean temperatures in bright weather are as high as those of any other cultivator because I allow a very high maximum. Very often, instead of giving air on every favourable occasion as the old calendars recommend, it is better policy to shut-up as close as possible when the sun shines in winter and early spring. This kind of forcing, however, requires more care and judgment than the old-fashioned way, but, at the same time, when properly done it is much more successful and far more economical.

All the air a house is likely to require during any part of the day ought to be given before the sun has shone on that house half an hour, and before the thermometer has risen 5°,

a little the instant the sun touches it, a little more in a few minutes when it is seen the mercury is inclined to rise, and so on by degrees, till as much is given as former experience has taught to be necessary. I would much rather a man under my command remained in bed all day than that he should commence giving air after the sun has been shining on a house half an hour. It may be thought I am running from my text, but it is not so, as I will endeavour to show.

The French Bean is generally supposed to be a likely home for the red spider, and probably many people never saw it forced through the winter without that pest. Now I have French Beans at the present moment in five houses in all stages, from those just peeping through the soil to others which have been in bearing some time, and there is not, and never has been, a red spider on them. This is almost entirely due to moderate night temperatures and giving air in a proper manner. Of course a very strict look-out for the enemy is kept, and it would be vigorously attacked on its first appearance. Prevention is much more economical than curing, as well as being better.

Another common way of checking plants and making them more liable to insect attacks is by using water which is too cold. In every well-arranged hothouse there is a tank in which the water is supposed to be of the same temperature as the house; but this is sometimes misleading to young men. Probably early in the morning it is sufficiently warm, but after the sun has been shining on the house, and perhaps on the pots in which the plants are grown, it is not so. It is always better, when it can be done, to water early in forcing houses, but when we are obliged to do it after the sun has been shining some time the water should always be tested with the hand if not with the thermometer, and it is better to have it a little too warm than too cold; while that for syringing should always be 5° warmer than the house.

One other way of propagating insects and I have done for the present. It is by neglect of forced plants—principally those forced for the sake of their flowers—after they have done their duty for the season. What becomes of them then? How are they treated? Are we sufficiently grateful to them for the pleasure and high encomiums they have brought us? Or do we forget them till we want them again? I am afraid many must plead guilty.—WM. TAYLOR.

DWARF PEAS.

According to circumstances, I am urged to allow all the air and light possible to circulate and shine upon my Potatoes: hence I eschew tall Peas and will venture to prescribe for folks having small gardens, to whom a maximum of Peas and a minimum of Pea-sticks and labour are compatible.

This (Woodstock) is a late cold soil. To secure a certainty of crop I do not sow Peas early, rarely till such time as the ground is become warmed by the spring sunshine, when the Peas will grow quickly out of the way of ravages from creeping things and others that hop. Referring to my note book of 1875 I find that I, on April 17th, sowed Maclean's Multum in Parvo, Laxton's Unique, Dr. Hogg, Supplanter, Connoisseur, Omega, and somebody or other's Robert Fenn, and Richard Dean Peas. June 26th, gathered from Unique and Dr. Hogg. The latter grows 3 feet. Unique grows 1 foot only in height, and is properly an early-border Pea, a site whereon it would have proven quite a week earlier. July 8th, gathered from Multum in Parvo; grows 3 feet. July 17th, gathered from Laxton's Supplanter and Richard Dean; each grows 3 feet high. July 24th, gathered from Robert Fenn; grows 3 feet high. July 31st, gathered from Laxton's Connoisseur and Omega. The latter grows 3 feet 6 inches high, and Connoisseur grew with me verging to 9 feet in height; we renewed taller sticks to it six times over, and it still cried for "more." I read its height on the packet as "3 feet;" it must have meant 8. It is a capital Pea for a garden of over 8 acres in extent; but for me, in my circumscribed sphere, "never more." I intend to substitute for it Turner's Dr. Maclean. The above, sown on the same day, served us with Peas daily and consecutively from June 8th to September 15th.

On May 2nd were sown Maclean's Multum in Parvo, Laxton's Omega, and Robert Fenn Peas. The first came into bearing by the middle of September, followed on the 1st of October by Robert Fenn, and from the 15th of October to the latter end of November, by Laxton's Omega, good and fine flavoured to the last. This and Connoisseur may be truly termed to-gather-and-come-again Peas, for on the 31st of July I picked

from my April sowings of them for the table, and in the middle of September I gathered my ripe seed, and Peas fit to cook from both the sorts. They will produce for a longer period than any other kinds that I am aware of.

This is a small history; but, according to my experience, it is of a capital assortment of Peas. Not always large and sweet, but Peas of various sizes, colour, and flavour, and each of them tender and very good. All the varieties mentioned above, with the exception perhaps of Dr. Hogg, are what are termed "branching Peas," and require to be sown thinly. My plan is to cast out a drill, with a narrow spade 4 inches broad and 2½ inches deep. Then place the Peas singly, in two lines, about 8 inches apart, in a triangular manner. The result I find quite worth the trouble.—ROBERT FENN.

FORCING ROSES.

For this purpose Roses on their own roots or on the Manetti are preferable to those budded on the Briar or Dog Rose; but good Roses can be produced from plants budded on the Briar. The best way is to take them out of the ground about the beginning of October, and pot them in medium-sized pots in rather rich but not heavy soil; by the middle of December they will be nicely rooted. They can then be pruned and taken to the house to be forced as wanted; but this should not be done very early the first year.

Roses which are required to bloom by the beginning of February should be pruned by the middle of November, and a week or two afterwards started in a temperature about 45°, increasing it to 60° by the time they flower. In fact a vinery started at Christmas is exactly the place to suit them. When the flowers have expanded they can be removed to the conservatory, which would be perhaps 10° lower. This will prolong the freshness of the blooms.

When the plants have done flowering they should be removed back again to the warmer house, where they must have as much light and air as they possibly can, and in a few weeks they will bloom again; and with care in keeping them free from mildew and green fly they will bloom the third time. The last time a very little before they come in out of doors. If a batch of Tea and Hybrid Perpetual Roses are placed in the same house to be forced, the former will flower some time before the latter.

After they have done flowering plunge them in ashes out of doors, and if any flower buds appear pinch them off, and in August take them out of the ashes, and lay them on their sides, keeping them rather dry, which will enable the wood to get well ripened by the time they are pruned. Care should be taken not to over-pot them, as that is one of the chief causes of mildew; but if it should appear syringe with soot and water, syringing again a few hours after with clear water, or dust with sulphur.—H. ETHERINGTON.

PEACH-BLOW POTATO.

New Potatoes—or, indeed, any new introductions in the vegetable world—must be able to run the gauntlet of adverse criticism, or they cannot establish their claims to support. Healthy honest criticism is most valuable and beneficial, and is, no doubt, equally appreciated by the vendors of new vegetables as by the public, for the "honour" of introducing anything new is not only empty, but in the end most damaging to its patron if the article proves new and "bad" instead of "new and good."

But criticism, to afford sound guidance, must be discriminating, and we must not, for instance, adjudge all American Potatoes bad because some of them may fail to be valuable, any more than we must regard all our American coins dishonest because one or two of them have been "tarnished sharp" with "other people's money."

Your reviewer of a pamphlet advocating the value of raising Potatoes from eyes has, I think, made rather "small Potatoes" of that innovation, yet I think that at least there may be some of the American Potatoes worthy of individual examination, to see if we cannot find a little corn amongst the chaff. In the aggregate the "foreign novelties" have no doubt been "over-estimated," but I think that verdict can hardly apply to the variety named. Peach-blow has not been unreasonably puff'd, and, so far as my experience goes, it is not only the best of all the American sorts, but is as good, and in some respects better than many of our standard English varieties. I have grown Peach-blow and found it good, and I have seen

it grown extensively by better growers than myself, and they and their customers have found it good also.

Your reviewer has mentioned Lincolnshire. Well, it is in that county where my experience of this sort has been gained. Mr. Lumsden of Bloxholm has, I believe, grown it largely, and if a Potato satisfies that cultivator I always have a suspicion that there is "something good in it." Unless I am in error Peach-blow has satisfied Mr. Lumsden. A neighbour of Mr. Lumsden's, a good and extensive grower of Potatoes—Mr. Frisby of Blankney—has I know also grown Peach-blow freely, for I have seen some wonderful crops of it in the Blankney gardens, and have heard Mr. Frisby extol its good qualities, and he, too, is a gardener not likely to be deceived. Further, I have known a farmer in Lincolnshire grow it by the acre, and although he charged the "tip-top" market price for the produce, such was the fame of Peach-blow amongst the consumers of the neighbourhood that the demand could not be met. I think it is fair to this variety, and to its introducers, that this statement of facts should be recorded.

Peach-blow is a round white variety with pink eyes, hence its name. It is a heavy cropper, ripening early, and is of good quality. It would be well to know if its good qualities and general usefulness under ordinary field and garden cultivation are sustained. My remarks refer to a period of three years ago.—J., Lincoln.

AURICULAS.

Your correspondent "ALFRED" asks me if I know where he can obtain a plant of Taylor's Glory and of Page's Champion. I regret that my reply is brief and disappointing. I do not know any grower at the present time, private or otherwise, who has plants of these two varieties to part with. I could tell "ALFRED" where the plants lie among the collections of members of the National Auricula Society; just as it is said that in the diamond trade the whereabouts of the finer gem is known to the jewellers; but if I were wanting Auriculas of such scarcity as the two in question I should consider the only equivalent would be the offer of some exchange with other sterling varieties of Auricula. Their money value even if their highest catalogue price were doubled is in the present scarcity of the flower no compensation. A guinea can be won over again, but an Auricula like Glory or Champion cannot be replaced.

I do not know the weight of character in "ALFRED's" collection, but if he be strong in one or two first-rate white or green edges, and would come to the National Auricula Society's Exhibition in Manchester next April, he would be welcome in the brotherhood that is so distinctly "florist," and might make his wants known to us.

In Auriculas I think more may be done in filling up a good collection by exchanges than by mere money. I should be sorry to melt down all my Champions and Glories at many times their money quotations, for they would simply be lost, and that which won them from me could not win them back. These two beautiful varieties both in habit of plant and quality of flower have not been seen much at the National Exhibition. They are both early risers in the spring, generally starting before January is out; they are both rapid in coming into flower, and have been always a week or so too forward with my own plants of them for a show in the fourth week of April.

They are models of the two styles of Auricula foliage, mealed and green; and the white edge of Glory and the green edge of Champion are splendid specimens of that most peculiar point of beauty in the florist Auricula "the edge."—F. D. HOBBS, Kirkby Malsard, Ripon.

OUR BORDER FLOWERS—LOOSESTRIFES.

Among the flowers of autumn none stand out more prominently than the family of Loosestrifes. Our subject, *Lythrum Salicaria*, is a most accommodating plant. Wild it may be, and quite at home by the rippling stream or the stagnant pool, and many secluded nooks away from the haunts of man. In shrubby borders or the wilderness, by the margins of pools or lakes, we can say of it "Always at home." Its cheering rosy-pink-coloured flowers are very attractive and effective at a distance. Being of pleasing habit the plant is suitable for the back row of a border.

There are other kinds that should not be passed by. *Lythrum roseum superbum* is a stronger grower than the first-named kind, and has larger flowers a shade or two darker in colour,

which makes it all the more desirable. *L. lanceolatum* is worthy of notice, and is a good plant for the shrubbery. *Lythrum lineare*, a white variety of much dwarfer habit and of more delicate constitution than the preceding, is seldom met with, but it ought to be sought after. It is a real acquisition to a choice collection of border flowers.

They are easily increased by division after growth has commenced in the spring, and are not at all particular as to soil. They thrive in most ordinary soils, and when established last for a long time. All the care they require when established is to leave them alone. Our native species are found on the strongest clay as well as the more genial loam.—*VERITAS*.

NOTES AND GLEANINGS.

MR. HUNTER of Lambton Castle is likely to add to his fame as a grower of Grapes the more rare honour of being a raiser of varieties of PINE APPLES. Mr. Hunter states (in "The Gardener") that his first batch of seedlings numbered thirty varieties, which were raised from seed accidentally discovered in a fruit. Since then Mr. Hunter has systematically and successfully fertilised the flowers of the Pine Apple and has obtained seeds. He is still continuing his experiments in this unusual field of cross-fertilisation and deserves the reward of success, especially as to manipulative skill must be added patience, seeing that "it takes twelve years at least to raise a stock off a single seedling Pine Apple."

—THE declared value of POTATOES imported into the United Kingdom last year was £1,071,518, against £1,085,589 in the previous year.

—THE range of SIZE OF TREES extends from the minute form of the Alpine Willow which we have picked on the summit of Skiddaw, of less than 3 inches in height, to the lofty column of the majestic Wellingtonia, which towers in the Giant Yosemite Valley to an altitude of 850 feet. A height of 200 feet is attained by the Umbrella Pines of Italy. In Solavonia the Sapin (*Abies pectinata*) attains an ordinary height of 275 feet. The *Eucalyptus Amygdalina* is described by Dr. Mueller as attaining on the banks of the Yarra River in Victoria the height of 420 feet in many instances. The Californian Big Tree is said to measure 96 feet in girth. In length of life and rapidity of growth the diversity is no less marked. A *Pinus sylvestris* from Finland 70 feet in height, and 72 inches in girth, has been found to register the passage of 518 seasons by its concentric rings. The venerable Yews that form a majestic avenue at Studley Royal, or the yet more magnificent patriarchs of the same species that form a kind of Druidic circle in the sequestered and beautiful glade near Guildford, known by the name of "Fairy Land," must have been in existence when the wood of the Yew decided the fate of battle in Norman or even in Saxon times. The *Eucalyptus globulus* on the contrary, rapidly attains gigantic dimensions. It has the property of absorbing ten times its weight of water from the soil, and of emitting antiseptic camphorous effluvia. When sown in marshy ground it will dry it up in a very short time, according to the evidence collected by M. Gilbert mentioned in the *Medical Times and Gazette*. In the spring of 1867 about 13,000 of the *Eucalyptus* were planted at Paddock, twenty miles from Algiers, in a plain situated on the banks of the Hamyze, and noted for its extremely pestilential air. In July of the same year, being the time when the fever season sets in, not a single case occurred; the trees were by that time 9 feet high. Notwithstanding this rapidity of growth the wood is of great strength and tenacity; and is to be obtained in any lengths.

—WE have the pleasure to announce that the Commissioners of the Cologne Exhibition have awarded to T. H. P. DENNIS & Co., Mansion House Buildings, London, and at Chelmsford, who were the only British exhibitors of horticultural buildings, a DIPLOMA, GOLD MEDAL, and 2000 marks for Victoria Regia house; also a DIPLOMA and 750 marks for heating apparatus for the same.

—M. CHATIN has lately called attention in the French Academy to some curious periodic movements in the LEAVES of the Conifer named *Abies Nordmanniana*, which are whitish on the lower, dark green on the upper surface, and are much admired. If the tree be observed early in the morning, or about sunset, the *ensemble* of the foliage seems uniformly whitish; whereas, in the course of the day, the green that seems very general. This is found to result from an alteration in the position of the leaves, so that they present now

their upper, now their under surface to the observer, and a diurnal position can thus be distinguished from a nocturnal one. M. Chatin has been studying these movements, and promises some further details regarding them shortly.

FRUIT FALLING INTO A NEIGHBOUR'S GARDEN.

RECENTLY in the Clerkenwell County Court, in the case of Patrick v. Allen, the plaintiff proved that five Pears worth 6d. each fell from one of his trees into the garden of his neighbour Allen. Allen threw them back into Patrick's garden, who sued for the bruising of the Pears occasioned by the throwing. The Judge said that Allen was not justified in so throwing them, and assessed the damage at 6d., and the costs were 18s.

On this case the following remarks have been furnished by a friend:—

Overhanging boughs and fallen fruit cause frequent disputes among neighbours, particularly in small suburban gardens. Let us consider what the rights of the parties are.

If A's tree overhangs B's premises, the entire tree and its produce belong to A. If therefore by natural causes the fruit, or a bough, or the tree itself fall on B's land, A has the right of re-capture, and he may get over the fence to recover his property.

But let A beware. When the law gives a man a summary remedy it watches him with such jealousy that if he does the slightest damage, or at all oversteps the absolute necessities of the case, the law withdraws from him the protection she accorded, and treats him as a trespasser from the beginning. It is better therefore to decline where you can the proffered favours of the law, for they are only snares. Distraint for rent, which is a favour of this nature, had become a most perilous proceeding until a statute of George II. restrained the Judges and brought them back to common sense.

Let A then ask B either to return his property or to show him where he can most conveniently enter the premises for the purpose of re-taking it.

The words I have used above, "by natural causes," must not be passed over as unmeaning. There is a difference between the case of a fruit falling from ripeness or a bough becoming detached by wind, and of a fruit falling by A's shaking the tree or a bough sawn off by him. The former is the act of Providence, the latter of A for which he must be answerable. Browne, in his "Legal Maxims," cites a case, but unfortunately without naming it, where a defendant, in clipping his hedge, had let fall some of the clippings on plaintiff's land. For clearing them off he was adjudged to have committed a trespass.

But has B no remedy? Yes, he can cut off the overhanging boughs, but for the reason given above let him not do so—at least until he has asked A to remove them himself. On his refusal let B cut them, taking care not to go a hair's breadth beyond the boundary line.

Or, as the land beneath the overhanging bough is rendered unfertile, let B commence an action on this ground for trifling damages. If after verdict A still defies him, he will, on a second action, get substantial damages.

No right of prescription can be set up by A, for boughs as well as roots are not fixed, but rove, and change their position and size from year to year. For this reason Gale ("On Easements") says, that there is no prescription as to roots, and the same argument applies to boughs also.

I have assumed throughout that A and B represent two separate owners. If they are merely tenants holding under one owner, the tree belongs to him and he should settle matters.

Having thus gone through the chief points as regards the legal rights of A and B, let me conclude by showing them a much more excellent way—namely, let A be allowed annually to gather his fruit, and let him leave a hamper of it at B's door as a token of thankfulness and good will.—G. S.

TUBEROUS-ROOTED BEGONIAS.—No. 2.

THE claims of these beautiful summer-flowering plants having been noticed, a few notes on their culture may appropriately follow.

FOR CULTURE.—The tubers should be potted in February in small pots, in soil consisting of two-thirds of good friable loam, the remaining third being equal moieties of leaf or light peat mould and silver sand. The drainage should be ample

and efficient. Water should be very sparingly applied until the plants have made some growth, but when they are growing vigorously a more copious supply is necessary. As they increase in size they should be shifted into larger pots, and the shifting repeated till the flower buds make their appearance. The temperature in which the plants are started should be from 50° to 55°, as the season advances this may be slightly raised. Under the conditions above stated fine specimen

plants in 8 and even 12-inch pots may be obtained from good tubers.

As soon as the flowering is over—which in healthy well-grown specimens lasts from two to three months—the tubers must not be allowed to dry too rapidly, or they will shrivel and weaken. They should be allowed to dry-off very gradually and afterwards be preserved in a cool but dry place; of course, free from frost.

Fig. 24.—*BEGONIA STELLA*.

GARDEN CULTURE—These Begonias have been proved to be grand additions to the summer flower border. To insure their flowering freely and producing flowers of good proportions, the border should have a south aspect, and particular attention should be given to the drainage, for these Begonias are sub-alpine plants, the parents of the best of the hybrid varieties, as *Begonia Veitchii* and *B. boliviensis*, having their native home on the Andes of South America at considerable elevations. They will be found to succeed best if the tubers are potted as described above, early in spring, in a temperature of about 50°, or for want of this in a cold frame, and, when the weather is sufficiently mild and the plants hardened-off, to plant them out where they are intended to flower. In sheltered situations, and in the south and west of England, a covering with fibre 2 or 3 inches thick will be a sufficient protection through ordinary winters; but generally it will be safest to treat the

tubers after flowering in the same manner as those grown in pots, by taking them up and drying them off gradually.

The following, introduced and raised by Messrs. Veitch and Sons, are undoubted acquisitions:—

Begonia Veitchii.—Flowers from 2½ to 3 inches in diameter, vivid vermilion. Figured in the "Botanical Magazine" for 1867, where Dr. Hooker says of it—"Of all the species of Begonias known, this is, I think, the finest. With the habit of *Saxifraga ciliata*, it has immense flowers of a vivid vermilion cinnabar red that no colourist can reproduce. It adds the novel feature of being hardy in certain parts of England at any rate, if not all."

B. intermedia.—A cross between *B. Veitchii* and *B. boliviensis*. A plant of vigorous habit and fine foliage. Flowers cinnabar red, deeper than *B. Veitchii*.

B. Vesuvius (figured last week).—A very profuse bloomer and

admirably suited for outdoor culture. Flowers bright orange scarlet.

B. Chelsoni.—A cross between *B. boliviensis* and *B. Sedeni*. Flowers a bright glossy red.

B. Sedeni.—A cross between *B. boliviensis* and *B. species*, a plant of free growth and robust habit. Flowers rich magenta.

B. Model.—A variety, the result of intercrossing *B. Pearcei*, *B. Veitchii*, and *B. Sedeni*. Flowers bright salmon suffused with orange.

B. Excelsior.—This variety has *B. Chelsoni* and *B. cinnabarina* for its parents. Its colour is very brilliant, a light orange.

B. Emperor.—This fine Begonia was exhibited last year at the Royal Botanic Gardens, Regent's Park, and at the Royal Horticultural Gardens, South Kensington. It received first-class certificates from both Societies. It is also figured in the "Florist and Pomologist" for December, 1875. It is of robust habit and foliage, and its flowers the most brilliant scarlet of the tribe. It is, I believe, not yet in commerce.

B. Acme.—Has also been before the public on several occasions, and attracted much notice on account of its brilliant colour, which is a delicate orange pink, and quite distinct from the other varieties, to which, however, it is a very welcome addition.

B. Kallista.—Is another fine robust hybrid with medium-sized flowers of a rich vermilion scarlet, the deepest in colour yet obtained. It is very floriferous, and an improvement on *B. Stella*, which is figured as representing a fine type of these valuable plants.

Where these plants do not flourish satisfactorily under pot culture it is almost invariably the result of growing them in too much heat. A sun-heated pit or frame is preferable in the summer months to a fire-heated stove, hence these plants may be successfully cultivated by all who have the conveniences of a cucumber frame and other ordinary structures, adaptable to growing Geraniums and other popular greenhouse plants.—W.

ABOUT MANY THINGS.

"Variety's the source of joy below."

AND first as to the great use of your paper—the help, the comfort, the friend it is to us all who take an interest in gardening. I had been for weeks in doubt as to what vegetable seeds and Potatoes I should order for my kitchen garden. I have been overwhelmed with seed catalogues, *vade mecum*, amateurs' guides, each one apparently more beautiful in their "get-up" than last year, full of every kind of information, but alas! perfectly bewildering in the number and variety of the sorts of Peas, Potatoes, Beans, &c. "What shall I do? What shall I order?" has over and over again been my cry, and I have kept putting off sending my small order till my friends will consider if I have out them. In the very nick of time, as a *very Deus ex machina*, your paper arrives, and I am relieved from my perplexity, for the very first article is headed "Notes about Potatoes," and there I find a selection of about six sorts, which will answer my purpose admirably, and the very next page contains an article from my evergreen friend, the genial "D. Deal," upon the vegetables which have succeeded with him during the last year, including a select list of Peas, which vegetable is my particular fancy, but which also is year by year the cause of greater perplexity from the extraordinary and ever-increasing number of sorts.

Then to turn to another part of "our Journal." I find the list of the fixtures of the horticultural exhibitions of the greatest boon, and one for which exhibitors cannot be too grateful. Among these entries one which brings to my mind an amusing scene last year. It is that of my native place, "Brighouse, July 29th, Messrs. C. Jessop and E. Bawnley, Hon. Secs."

Mr. Baring Gould opens his capital work on "Yorkshire Oddities" by saying, "every Yorkshireman is an oddity," and there is more fun to be had in that county than any other I have been in. I happened to arrive the day before the last Show, and was greeted by, "Why you have come just in time for our show." Early next morning I accompanied one of the Committee to the show ground, and never before did I see such a wonderful place for a horticultural exhibition. At one side was erected an enormous grand stand with beams and joists fit for the sons of Anak to sit on, and all over this stand was to be found a printed paper certifying that "We (two practical carpenters) have examined this stand, and certify that it is of

sufficient strength and stability." In front of the stand immense barricades separated a large portion of the field. This is for the jumping. Jumping? Yes, leaping. We have prizes for hunters, &c., as well as for flowers. At the other side of the field was an enormous tent, as large as those we usually see down here, which contain the flowers. "Is that the tent for specimens?" "Oh, dear no, they are all in one tent—that is for the refreshments." And, gentlemen, it would have astonished you if you had seen the preparations for so supplying the needs of our jolly tykes. The very tables were supported on beer barrels, a most ingenious arrangement as they performed the double purpose of supplying two kinds of support. There was as much beer that day consumed as would have kept my parish well supplied for years.

Then at last we came to the flower and vegetable tent, and what a wonder it was. Of enormous size, filled with a struggling, gesticulating, shouting mob, no policeman to keep anything like order. No one to prevent all the boys and girls of the town coming in. There they were all together, exhibitors without coats, committee-men screaming, "Here, lads, any more Beet-roots?" "Now, then, three sticks of Celery here!" And then a sudden charge was made on the populace by some indefatigable member of the Committee, who proceeded to what we call "poise" a few small boys, who immediately returned to the same place directly his back was turned. "Why in the world don't you have a policeman to keep order?" I asked. "Oh! they said they would not come unless they were paid, and we are not barn to pay them."

On one table, however, was a most miscellaneous collection of things. Joints of meat, hats, churns, whips, bridles, boxes of cigars, and even a cake covered with sugar were displayed. "What are these?" "Oh! those are some of the prizes given by the tradesmen." "And what is this?" "Oh, that's an 'air pad.'" "A what?" "An 'air pad.'" "Oh," I said, "you mean one of those things they put on chairs for invalids." "No, I doant," he roared out, "I mean chignons, pads for the 'air of the 'ead.'" The flowers were really wonderfully good, considering what a climate we have there. The Show was a most decided success, and attracted vast numbers of visitors.

And now a few words about Rose shows for the coming year, and first as to the Royal Horticultural Society. Here I know I am on delicate ground, but surely the fact of one of you being Secretary will not close the columns of our Journal to any criticism of the Society. And we rosarians have really just cause to be indignant, for the Rose show proper is conspicuous by its absence from the Society's schedule. There are a few miserably small prizes for Roses given at an exhibition late in July, but there is no Rose show in which the National Rose Show is incorporated. And why not? If any show succeed it must have been the Rose one, for the arcades were always crammed with people. And why should the Rose be left out in the cold when flowers in every way her inferiors are to have their special days? It is an insult to the queen of flowers, and I shall leave the Society in disgust, and without a regret. Why, gentlemen, if it had not been for the Westminster Aquarium filling the gap, London would this year not have a Rose show, for that miserable affair at the Royal Botanic is not worthy of the name. Do try and alter this at Kensington, use your influence in preventing this slight being paid to our queen of flowers. With the exception of the B.H.S., societies are offering more liberal prizes for Roses. The schedule of the Westminster Aquarium is a most liberal one, and at Maidstone the same large prizes of £15 for nurserymen and £10 for amateurs are offered. Frome offers grand prizes for the open classes, and numbers of other societies follow suit. Every day the enthusiasm for Roses is increasing, the sale at the well-known nurseries is so great that the proprietors have to purchase large numbers to supply their customers.

The last year brought out an amateur who will soon be *nulli secundus*. I allude to Mr. Jowett of Hereford. If he does not have very late frosts this season he will show marvellous blooms. I never in my life saw such growth as his blooms proved at the shows, except that of his great neighbour Mr. Cranston. He has the same grand soil as the latter and is as enthusiastic as any of us, and will make it hot for us in the west whenever we meet.

We are having the most violent changes in the weather down here. A week ago it was bitterly cold, though hardly any snow fell, and now it is so mild that the birds sing all day, and the Roses are beginning to show signs of returning life. I am afraid we shall have cause to rue this present state of

things; but perhaps they have the same weather in the neighbourhood of Hereford, and if so we need not complain.—
JOHN B. M. CAMM, *Monkton Wyld.*

HAWTHORNDEN APPLE.

"C. R." has at least one "brother in misfortune," for I have experienced precisely the same disappointment as that detailed on page 74. The soil in which I have made strenuous endeavours to grow the Hawthornden Apple is light in texture, with a marly and not well-drained subsoil, but yet not so much soddened as to prevent many sorts of Apples growing satisfactorily. On this point I can say with "C. R." that "with the exception of Ribston Pippin and Hawthornden no other Apple cankers here."

My employer being particularly desirous, I might almost say determined, to establish healthy trees of Hawthornden, I paid special attention to them, but without avail, and after trying for twenty years to obtain healthy trees of this coveted Apple the project was abandoned in despair.

The soil, as I have said, is light; but in an adjoining parish, where the soil is of a sounder character and deep, I have seen Hawthornden trees tolerably free from canker and bearing heavy crops of fruit. This is different to the experience of "C. R.;" but yet after special observations in different parts of the country, I have arrived at the conviction that to cultivate this Apple successfully it must have a generous and well-drained soil.

I am not certain that canker is not what I may term a local hereditary disease, for in grafting the Hawthornden on healthy stocks the scions from cankered trees have been more speedily overtaken by the disease than have others taken from trees which showed little or no canker. That is a subject worthy of some consideration, as being a probable source of failure exhibited by certain fruits which refuse, as a rule, to prosper in some localities. That fruits have their caprices is tolerably certain, and it is generally well to profit by them and to plant those sorts principally which seem to have a fancy for certain districts.

I may further note, that in endeavouring to establish satisfactory trees of the two popular sorts named in a garden to which they had clearly a great amount of antipathy I always found the advantage of Paradise over Crab stocks, perhaps because the roots of the former did not so quickly penetrate the ungenial subsoil as those of the latter. Be this as it may, the trees worked on Crabs cankered the soonest and the worst; but on neither, after many years of trial, is one really healthy tree of Hawthornden to be found in the garden where the kind has been so particularly desired.

I am glad "C. R." has mentioned this proneness to canker of a popular Apple which is credited with a sounder constitution than it probably possesses. Although others may prove the contrary, I am, by the light of my own experience, bound to regard the Hawthornden Apple, not as a constant and vigorous kind, but on the contrary one that is capricious and uncertain, and not to be relied on except in particularly good, well-drained, and deep soil. What do others say?—AN OLD GARDENER.

METEOROLOGICAL AND OTHER NOTES ON 1875 AT LINTON PARK, KENT.

LIKE a tradesman taking stock of his goods at the end of the year, we may also review the past season and judge of what it has bequeathed us for the current year.

January, 1875, was ushered-in with a hard frost and a good depth of snow, but which left us in a day or two, the rest of the month being mild. February proved dry though cold, and was on the whole a fine month. March was much the same until the last week when milder weather set in, which continued with the usual interruption of frost until the end of April. May was a dry month though not by any means a warm one, and vegetation had not the promising look at the end of it it had at the beginning. June opened more summer-like, and some useful rain in the middle of the month did much good, yet on the whole the prospects were gloomy, not so much from the lack of rain as from the absence of sunshine so essential at this season, and many kinds of vegetables fell short of what was expected, and also the hay crop.

July brought heavy rain, but not too much in our neighbourhood, as we had not any of the disastrous floods recorded elsewhere, although on the 15th and 16th of that month we

had 0.95 and 1.45 inch of rain, less than one-half of which would have given us a flood in winter, but which on this occasion only filled our rivers; and as rain was much wanted everywhere, the copious downfall of July was of much service all the rest of the summer. Some forebodings, however, of an ominous kind were not wanting of how it would affect the crops, but the last ten days being dry and fair, and August an exceptionally fine month throughout, the harvest was on the whole well secured, and fruit ripened satisfactorily, the fine weather continuing up to the 21st of September, the 18th of that month being the hottest day but one we had during the summer, and, in fact, from the 20th of July to the same time in September might be said to be the only settled summer we had; after the latter time the autumn rains gradually set in.

October was a wet month yet not remarkably so, nothing like the same month in 1872. November was wetter, and the last week of that month ushered-in winter in the shape of several inches of snow, which received fresh accessions the first week in December, with sharp frost, making an early winter; but milder weather set-in after the 10th, and we had no frost at all after the 14th, up to the 5th of January of this year, an unusual thing in the shortest days, while it was remarkably mild some days, the thermometer recording 51° on Christmas day, and 54° on the 22nd. This mild weather was, nevertheless, not without its inconvenience, the lack of sunshine the whole of the autumn and up to the end of December has told sadly against forcing, and it has been no easy matter to prevent Geraniums and similar plants damping-off in greater quantities than usual, which the reviving influence of sunshine does more to prevent than any amount of fire heat. One redeeming quality, perhaps, the expiring year has bequeathed to us, and that is, the ample rainfall is likely to tell on our springs and other sources of water supply for the current season, and we may look hopefully to the future, for as will be seen by the following table, the total rainfall has been an ample one on the whole.

	Rain in ins.	No. of Rainy Days.	No. of Frosty Days.
1875. . . .	50.35	157	72
1874. . . .	33.49	143	83
1873. . . .	33.99	139	78

Average for 30 years .	35.39	135	58

—J. ROBSON.

HORSERADISH.

THIS is an important, yet frequently is a very abused or neglected crop. Horseradish is always in demand in winter and summer, but the beds, as a rule, receive but scant attention. Common is it for a man to grope half an hour, perhaps, in frost and snow picking and digging for a "stick" that he is ashamed to show the kitchen maid, spoiling, probably, twenty crowns in his endeavour to find one or two useful bits of roots. By the loose mode of culture often adopted much ground is wasted; in fact, the beds frequently have no culture at all. The crowns exist because they refuse to die, and spread over a five times greater extent of ground than would suffice with good cultivation.

I used to trench the ground 2 feet deep and place the crowns nearly at the bottom of the trenches, and so obtained good roots, but not, I thought, worth the labour they had cost. I then made holes with a crowbar to the same depth, dropped in sets or crowns, and filled-up the holes with leaf mould, and so saved much labour, and had equally good "sticks." But both those plans entailed much labour in taking up the crop. The Journal then came to the rescue, and a mode of culture was given by Mr. Willis which I at once adopted and have never departed from. That is some years ago, and time has proved the value of the plan.

I now form a ridge of soil—garden refuse, old tan, manure, indeed any vegetable refuse that is handy. The ridge may have a 3-foot base and be 2 feet high. In the sides of this the roots are planted alantingly. Roots are selected about a foot long or more, and of the thickness of a tobacco pipe. These are slightly scraped (as if for the table, but more lightly) to remove the eyes, and are inserted perfectly straight, their crowns just being level with the soil. These smooth straight roots thicken and form splendid roots that can be dug with comfort and be carried through the garden in broad daylight without any sense of shame.

I have found no plan comparable to the ridge mode in raising Horseradish, none so economical, effectual, creditable, and comfortable. I generally make a fresh ridge every two or three

years, but to grow "sticks" to the greatest perfection the ridges should be renewed annually, and should consist largely of manure. I am sure this rational mode of growing creditable Horseradish is worthy of more general adoption. It is surprising what a large supply of roots may be raised from even a small extent of ridge. No time is better than the present for planting the roots.—W. B. J.

OLD APPLE TREES.

I HAVE read with much interest "RADICAL CONSERVATIVE's" articles entitled "Old Trees," but in regard to them he seems more "conservative" than "radical."

He kindly refers to a passage on this subject in my "Christmas Greeting," and I think I must ask space to give a few words of explanation.

First, I alluded only to Apple trees planted in vegetable gardens and not growing on grass. Secondly, only to old trees of inferior varieties and which cropped badly. I am fully aware of the value of old and good trees, but in this part of England in cottage and farm gardens, as a rule, the Apple trees are of local and inferior varieties. When I see old straggling, moss-grown, useless, or half-useless, trees shading a bit of land which but for them would grow vegetables that would go towards many a dinner for a cottager's family, I always urge their removal; but I am met with the "Conservative" objection—"Well, there now, sir, they have been there this many a year." And so the trees remain.

The two trees that paid the rent of the cottage mentioned by "RADICAL CONSERVATIVE" were the opposite to these; and his loss partly arose, as I think he seems to imply, by having his dozen pyramids of various sorts and not of one or two.

Having become much interested in hardy fruits I seldom pass a tree, or see an Apple or a Pear, without taking special note of them. As with Roses so with Apples, handsome and good varieties will no doubt find their way into small gardens, and these will be more profitable. Why is the Blenheim Pipin so popular? Because it is beautiful as well as useful. I would that in all fruit catalogues Apples should be specially marked as "handsome and useful." Soft wretched Apples, neither good to eat nor good to cook, and having no good looks to recommend them, are still—in this part of England at least—far too commonly met with. "An Apple is an Apple" still with many, and I desire to see an improvement in this branch of horticulture. I do not speak of large trees in orchards, but of small trees in kitchen gardens, specially in the gardens of the poor. Handsome and good fruit would command a better price, and the neatly-dressed cottager's child with her basket of such fruit would bring home "more money to mother" than such as are generally grown. But how is this to be accomplished? Orchard trees are long in becoming productive, so I again say by recommending pyramids.

Passing by small gardens, I am inclined to think that Apples are not thought enough of even in large gardens. Upon inquiry I often have the answer that—"We are not well-off for Apple trees." This should not be, now that good varieties are easily to be had and when fruit-growing has become an art.

"RADICAL CONSERVATIVE" speaks of trees not coming "true to name." This is most vexing, but perhaps to be excused at "an auction sale." I have my tale to tell on this subject. About twenty years ago when I came to this place I found the garden in a bad condition as to trees, so sought out a neighbouring nurseryman. (I like to deal with my neighbours. I go to no Civil Service stores on principle. Live and let live—not kill tradesmen—is my rule.) I ordered named Gooseberries of different colours. I like the contrast of colour on a desert-dish. I ordered Plum and Apple trees, and one specially—a Junceating for my children, remembering how I liked that early toothsome Apple when I was a boy. Well, hear the result. My Gooseberries proved all of one colour; Coe's Golden Drop Plum came a small, poor, yellow Plum of bad flavour; and my Junceating turned out to be a Hawthornden, which I already had. Mark you, all these trees bore their labels white and flaunting on them. N.B.—I did not trouble that nurseryman again, especially when on my complaining he said—"One sort is just as good as t'other." I feel bound to say since the old man's death his nursery, in the care of a young enterprising man, is conducted on wholly different principles to the anything-will-do system. However, to continue my story, being determined recently to renew my garden and wishing to be quite sure this time, I had my trees from Mr. Richard Smith

of Worcester, knowing that every tree from him would come "true to name."

Leaving orchards quite out of the question, I am sure that the cultivation of hardy fruits in gardens of moderate dimensions, and I may add by amateurs of moderate means—in fact, in such gardens as are usually attached to the parsonage, and by men of such means as the general run of clergy are—is a very agreeable pastime, adds interest to a garden, and pays its expenses. We have not all vineries or even greenhouses, but we clergy in the country have all of us gardens walled or unwall'd; if the former all the better, if the latter we can take refuge in pyramid Apple, Pear, Plum and Cherry trees, and mark and watch their growth and progress; take notes of appearance and flavour; fill up many a spare minute profitably and healthfully in the open air; and, more than all, increase our knowledge; and an increase of knowledge always brings an increase of pleasure. This is what I seek for myself, and this is what I wish others to enjoy as well as myself. The country is never dull to those who have eyes and well use them, and active minds that are always adding to the knowledge of their owners.—WILTSHIRE RECTOR.

I FEEL considerable diffidence in sending my opinion on the subject of old trees, because I am not by any means a learned gardener, and have never before written on any subject belonging to the profession. If you were to take me into a conservatory I should probably not know the names of one-fourth of the plants therein; but I was born in a large orchard and lived in it, I might say, for the first twenty-five years of my life. I began to prune Apple trees, &c., as soon as ever I could use a tiny saw, my father standing below and giving orders.

Now I must say that I entirely agree with "RADICAL CONSERVATIVE" in all he has said on this subject, and I must venture to differ with Mr. Robson, because my experience has taught me that an old tree if healthy in the trunk and main branches may often be grafted and form a fine tree, and bear first-class fruit in far less time than similar fruit can be had by planting new trees. For instance, the only trees we had of Blenheim Pipin were grafted on old stocks; I cannot remember the time they were grafted, but before I was old enough to notice such things, but when I left them they were large trees bearing good crops of the finest fruit I ever saw.

Again, we had a row of Manks Codlins which produced plenty of fruit, but so small as not to be worth gathering; they were knotted, and gnarled, and eaten up with American bug, but on being "buckheaded," as we used to call it, and the stumps well dressed with lime, soot, cow dung, &c., they threw out strong shoots and a great many of them—of course the weakest were "rubbed out"—and in a very few years they were fine healthy trees, bearing good-sized clean fruit fit to go anywhere.

I know one tree of a kind known in the east-midland counties as Normanton Wonder (What is it called elsewhere? In my opinion the best winter Apple for kitchen use grown).—[Dumelow's Seedling and Wellington.—Eds.] It was blown down flat to the ground, and although the trunk was nearly 18 inches in diameter the top was cut off, and the stem reared upright and securely propped, and when I saw it last it had grown sufficiently to produce about thirty pecks of as fine fruit as anyone need wish to send to market.

I could multiply examples on this subject if it would do any good, but space and time will not allow. My advice to any who have standard fruit trees is this—If of a good kind, but growing small fruit, "buckhead" them, and if you wish to change the sort graft them with something else, only mind that it is something better. A very few years will show whether they will make good trees again or not, and then when you have tried them, if they do not promise fairly, say, "Cut them down. Why cumber they the ground?"

I may add that I had some Damson trees that had been "buckheaded," and they had grown again into large trees bearing splendid fruit.—J. J., Lancashire.

THE REV. H. COTTINGHAM'S GRAPES.

EVERYONE who cultivates a garden as a source of relaxation and pleasure has some object of which he makes a special hobby. There are not a few who "go in" for Roses and bestow on this queen of flowers unremitting attention. Others, not so refined in their tastes, and who wish to blend the useful with the ornamental, have a fancy for growing certain

vegetables, such as Onions, Leeks, and Celery; while not a few who can raise a glass house, however small, make the Vine a special object of culture. I have known tradesmen, in the midst of a thickly populated town, surrounded by high brick walls, with only space at command for a house 10 or 12 feet square, and a few feet outside for a border, who have produced Grapes both in size and finish that would grace the table of a duke.

A short time ago I saw the splendid crop of Grapes in the gardens of the Rev. H. Cottingham, Rector of Heath, near

Chesterfield, and I can safely say that scarcely finer Grapes could be found within a radius of 100 miles. Mr. Cottingham is an amateur in the strictest sense of the term, not employing any skilled labour; but he is an amateur of no mean order, and I place this instance of success on record to stimulate those who have hitherto failed in the culture of the Vine, and to encourage those amateurs who would be pleased to grow a few Grapes but dare not embark in their cultivation.

The village of Heath is pleasantly situated on the brow of a lofty hill, about $4\frac{1}{2}$ miles from Chesterfield and $7\frac{1}{2}$ miles from

Fig. 25.—THE REV. H. COTTINGHAM'S GRAPES.

Mansfield. It is a neat agricultural village, and the church is a handsome stone building, and has a tower surmounted by a fine spire and set of bells. From the drawing room and flower garden of Mr. Cottingham we obtain charming views of Hardwick Hall and the park, with its venerable Oaks. Turn in which direction we may the whole scene is full of interest.

Adjacent to the drawing-room is the well-kept lawn, and at convenient distances from the windows there are fine specimens of *Cedrus Deodara*; also groups of golden Yews and variegated Hollies. These, as the late Sir Joseph Paxton used to say, are the chandeliers of the pleasure ground, and truly they give beauty and interest to the garden at this dull season, when the destructive 'Ice King' has laid prostrate all its floral treasures.

It was, however, the vineries I went to see and the magnificent Grapes. The Vine-houses at Heath are not of large dimensions, both together being 60 feet in length, with a glass partition in the centre. They are 18 and 10 feet high, and heated with hot water. One house was built and planted twelve years ago, and the other was added and planted two years later. The border for the first planted Vines is on the outside of the house, and the latter planted Vines had a border both inside and outside. It is worthy of remark here that those Vines planted in the border outside have always been very much superior to those planted in the inside border. This is rather damaging to the theory of many of our celebrated writers on the Vine, who recommend so strongly that Vine borders should be made within the house in this our vari-

able and uncertain climate. However, the first planted Vines were so much superior to the last planted canes that the worthy Rector last spring resolved to uproot the latter, make a fresh border, and commence with new Vines. The roots of some adjoining Beech trees had also found their way into the border, and they were appropriating the food which otherwise ought to have gone to the sustenance of the Vines.

The new border is formed of much the same material as the old one, being composed of good sound turf, broken bones, charcoal, and old mortar rubbish. To one load of turf was added one peck of bones, half a peck of charcoal, and a proportionate quantity of old mortar. The border is concreted underneath, that is covered with 1 foot thick of broken stones, and then the above compost. The new Vines were struck from eyes in February, planted in May, and after they had reached the top of the house and gone to rest they were cut down within several inches of the ground. The sorts planted were one Golden Queen, two Black Hamburgs, one Madresfield Court, and one Gros Colman. Among those that remain are Black Hamburg, Muscat of Alexandria, Canon Hall Muscat, Pearson's Alicante, and Barbarossa.

When the Vines were young it was not unusual for the bunches of Barbarossa to weigh 9 or 10 lbs. each, Muscat of Alexandria 8 lbs., and Alicante 6 or 7 lbs. On the 18th of January there were some fine bunches still hanging. The Muscats were a fine amber colour, and the bunches would be nearly 4 lbs. each, Alicante 3 lbs. each, and the Barbarossa would be about 7 lbs. each; the berries plump and perfect, and they looked as if they would hang for months to come. Mr. Cottingham evidently brings a vast amount of skill to bear upon the culture of the Vine. He treats it in a common-sense sort of way, and duly receives his reward. I have many times visited places of much larger pretensions, but never where more satisfactory results were accomplished.—R.

P.S.—The engraving represents the Vines when both houses were in full bearing.

TRAINING YOUNG FRUIT TREES.

MR. DOUGLAS on page 69 has given instructions on the training of young Pear trees on the horizontal cord system, recommending it as the best mode of training for these trees. His instructions are to take the central shoot upwards and to train the side shoots along the brick courses, stopping also the leading shoot in the summer, and so obtaining two or more pairs of side shoots the same season. That is a valuable hint which will not be lost by those who have healthy young wall trees. Too often the tall central shoot is left until the winter pruning, then to be cut away after having done its work by appropriating the strength from the side shoots and wasting the energies of the trees.

But yet I think it is not well that the instructions given by Mr. Douglas be followed literally. The horizontal system may be the best mode of training the branches of Pear trees, but is not the best, I think, when the trees are young. With some trees of exceptional vigour the system is perhaps not very objectionable, but with ordinary trees it is not the quickest, but perhaps the slowest mode of covering a wall to train the branches of young trees horizontally.

The first trees that I nailed were young Pears trained along the seam-courses, and after seven years the wall was not half covered. To induce a free growth the fan system of training is much preferable to the horizontal, lowering the branches by degrees as the trees gain strength. I have very little doubt—indeed I have tested it by direct experiment—that by training the branches more or less upright for the first four or five years of the tree's growth that a great gain is effected in covering a given space of wall. The branches can be brought down as required, and when the trees have attained a considerable size, and the depression will probably expedite their fruitfulness.

In training young trees a point of the greatest moment is to secure the extension of the lower branches and to keep them in advance of the branches above them. It is very difficult to do this by a rigid adherence to the horizontal training of the branches along the seams of the wall, and especially when the trees are young. If, as is often the case, the lower pairs of branches do not make the same lateral extension as the branches above them when the trees are young, the wall cannot be well furnished afterwards. The most effectual way to prevent this is to train the weaker branches more or less upright, depressing the stronger growers. By a systematic mode of

elevation and depression a correct balance of the tree can be attained, and I am not aware that it can be secured by any other means.

To induce a free growth of wall trees in their young state, and to cover space in the quickest manner, I have invariably found great advantage in training on the fan-shape system, keeping the weaker parts more or less upright and giving special attention that the lower branches are kept well in advance of the parts above them. By five years' training on this system with a wall of Pear trees, and then bringing the branches to the horizontal positions, I have produced much larger and healthier trees than some others that were trained horizontally from the time of planting.

I have no doubt that many others have also noted the advantage of the fan over the horizontal training of Pear trees in their young state, for there can be no doubt that it does possess advantages of practical importance and which should not be overlooked.—A NORTHERN GARDENER.

NEW BOOK.

Domestic Floriculture, Window Gardening, and Floral Decorations. By F. W. BURBIDGE. With Illustrations.

THIS second edition is enlarged, and is deserving of purchase by everyone who wishes for good information on the subjects of which it treats. We shall only extract an historical portion:—

"The science and art of window gardening, as well as the use of decorative plants in apartments, is, as yet, in its infancy, and its early history seems shrouded in obscurity, although fifty years ago plants were commonly grown in cottage windows, those more generally employed being *Fuchsia globosa*, Fair Helen Geranium, Musk, several *Mesembryanthemums*, Cactuses, and crimson China Roses. More recently, the newer varieties of *Calceolarias*, *Fuchsias*, *Campanulas*, *Balsams*, and *Pelargoniums* have been employed; while, at the present time, we employ Figs, Palms, Ferns, and the very choicest of exotic plants for the indoor decoration of our dwellings, amid the dust and bustle of the busy city. Domestic floriculture exerts an influence that contributes much to our comfort and happiness in the smoky atmosphere of a town residence. Looking at the subject from a commercial point of view, we find many large establishments devoted entirely to the culture of decorative plants in small pots, while thousands of pounds are spent yearly in London for the pretty little decorative plants so often met with in the window cases and apartments of town mansions. We look on the decoration of our dwellings with healthy plants and fragrant blossoms as the sign of a more healthy appreciation of nature, as the embodiment of all that is beautiful and attainable in art.

"Amongst the oldest and best-known window plants used in this country of late years, we may mention *Fuchsias* and *Hydrangeas* (which latter occasionally astonished their possessors by bearing blue flowers in place of rose-coloured ones). *Tussilago fragrans* is also mentioned as being 'planted in pots for the purpose of perfuming winter apartments;' while *Cyclamens*, *Auriculas*, and *Myrtles* were common many years ago. *Richardia* *æthiopica*, or *Lily of the Nile*, was grown by Miller in the Chelsea Botanic Garden as early as 1731; and in the 'Flora Historica' (1824) we read that 'the more polished part of society admit the Ethiopian Calla, a species of *Arum*, into their most embellished saloons, where its alabaster calyx expands into so elegant a vase-like shape, that *Flora* seems to have intended it for the hand of Hebe, when she presents the imperial nectar to Jove,' adding that 'the fashion of ornamenting the houses in London with plants when routs are given greatly contributed to bring it into celebrity, and as a conspicuous candle-light plant it was therefore increased by all rout-furnishing florists.' *Campanula pyramidalis* was also an extremely popular window plant fifty or sixty years ago, being frequently employed by country people then as now to decorate their windows; or when trained round a hoop, or into the shape of a fan, it sometimes served as a screen 'to the rustic grate of a country parlour.' This is the 'Steeple Milky Bell-flower' of Gerard, and has been grown in our gardens nearly three hundred years.

"Cowper, in the 'Task,' celebrates *Mignonette* as a favourite window plant in London during the latter part of the last century—

"The shades fringed with a range
Of Orange, Myrtle, or the fragrant weed;"

and Philips in his 'Flora Historica' says, 'We have frequently found the perfume of the *Mignonette* so powerful in some of the better streets of London, that we have considered it sufficient to protect the inhabitants from those effluvia which bring disorders in the air.' The latter statement is remarkable, inasmuch as recent researches prove the beneficial influence exerted not only by this but by many other odorous flowers; and we

are now recommended to plant Sunflowers (*Helianthus*), and the Fever or Blue Gum Tree of Australia (*Eucalyptus*), as a preventive of pestilential diseases in marshy or malarious localities.

"Chrysanthemums were introduced in 1764, and again in 1796, and, like the Roses of China, the Chrysanthemums soon escaped from the conservatories of the curious, and as rapidly spread themselves over every part of the island, filling the casements of the cottagers with their autumnal beauties." It is rather singular to find that the 'Winter Cherry' (*Physalis alkekengi*) has been grown in our gardens as a decorative plant since 1548, or above three hundred years ago; and it appears to have been commonly grown in the time of Gerard, who quaintly tells us that 'the Redde Winter Cherrie groweth vpon olde broken wals about the borders of fieldes, and in moist shadowy places, where some conserve it for the beaultie of its berries, and others for the great and worthy vertues thereof.'

"Phillips, writing in 1824, says, 'At present the berries are seldom used with us, excepting to mingle in bouquets of dried flowers, or to ornament the chimney-pieces of cottage parlours.'

"*Lobelia* of the *L. cardinalis* section were esteemed many years ago as window plants, and China Asters were also used occasionally in pots and boxes for a like purpose; while the Blue Throatwort (*Trachelium cornutum*) was often used as a decorative plant, not only in pots, but also partially naturalised on old walls, along with Snapdragons (*Antirrhinum*) and Wall-flowers (*Cheranthus*).

"*Balsams* (*Impatiens*) have been grown in our gardens for the last three hundred years, and have long been esteemed as decorative window plants by cottage florists.

"*Convolvuli*, both *C. tricolor* and *C. major*, were known in the time of Charles I.; for Parkinson (1629) tells us that he received seeds of the former out of Spain, and that the flowers are 'of a most excellent skie-coloured blew, so pleasant to behold that often it amazeth the spectator.'

"*Succulents*, as *Phyllocactus* ("Cactuses"), Cape Aloe, more especially the well-known *A. variegata* introduced in 1730, and many species of *Mesembryanthemums*, have long been cultivated in cottage windows. Another old sweet-scented favourite, *Aloysia citrodora*, was introduced in 1784, and is still very generally grown as a decorative plant; while some of the earliest varieties of fancy or hybrid *Geraniums* (*Pelargonium*) soon found their way from the gardens of the florist or wealthy amateur into cottage windows, where their more beautiful representatives still remain.

"The well-known "Aaron's-beard" (*Saxifraga sarmentosa*) was introduced from China in 1771, and is still one of the most popular of all window plants on account of its free habit of growth and vivacious mode of reproducing itself. Many more examples might be given, but the above rough sketch is sufficient for our present purpose. We have shown the custom of employing flowers and living plants for purposes of domestic and personal ornament to be an old one; while at the present time they speak a language peculiarly their own, and enter largely into the expression of the joys and sorrows, the light and shade, of our everyday existence. Window-gardening has spread from humble cottages to the mansions in our busy towns, and on all sides we have societies fostering a love for the more extended culture of decorative plants among all classes of society. The indoor cultivation of plants and flowers has especial attractions for the invalid, and the interesting employment thus afforded serves to brighten or while away many a tedious hour. Even a few cut flowers and fresh leaves or sweet-smelling herbs kept in water, afford relief to the eye of the sufferer, and help to divert it from wandering over the cheerless walls of the hospital, or from peering into the deep shadows of the sick room.

"The pure and lasting taste for beautiful plants and flowers, if firmly implanted in the human mind, almost invariably exerts its beneficial influence for good; hence gardening ought to be made use of in connection with all our public schools as an educational appliance of the highest possible value. In Sweden the elements of horticulture are systematically taught in all government schools; and we believe great results would follow, from a national point of view, if the rudiments of gardening and its sister art farming were practically taught in this country more generally than is at present the case.

"Throughout France, again, gardening is practically taught in the primary and elementary schools. There are at present 28,000 of these schools, each of which has a garden attached to it, and is under the care of a master who can impart a knowledge of the first principles of horticulture. Even in the schools to which no garden is attached the theory of cultivation is taught; but it has recently been decided by the Minister of Public Instruction that the number of school gardens should be largely increased, and that no one shall be appointed master of an elementary school unless he can prove himself to be capable of giving practical instruction in the culture of the soil.

"Many who have no little garden wherein to grow a few sweet-scented flowers, yet manage to extemporise ways and

means to gratify the love of nature, which appears to be nearly universal. Window gardening has doubtless been practised for centuries under difficulties, and the garden poet alludes to the practice in the following lines:—

"There the pitcher stands
A fragment, and the spoutless teapot there;
Sad witnesses how close-pent man regrets
The country, with what ardour he contrives
A peep at nature when he can no more."—COWPER.

ROOT-GRAFTING STONE FRUITS.

It is common in root-grafting the Apple to make two or three stocks from one seedling root. This manner does not work so well in the case of stone fruits. I find no difficulty, however, in root-grafting stone fruits. For the Peach, Plum, and Apricot I use the wild Plum for a stock. I take up the seedling Plums in the autumn, being careful to break off as few of the small fibrous roots as possible. I put them in a cool cellar, packed in earth, and leave them there until I wish to use them during the winter. When these roots are grafted I keep them moist and do not expose to cold. I use the whole root of the seedling, from 6 inches to a foot long to make one root-graft, whip grafting near the collar. The grafted roots are then packed in earth, in the cellar, to be planted out, after the ground has ceased to freeze, in the spring. The success or failure depends greatly upon the amount of small roots upon the seedling stocks. Stocks that have been once transplanted are still more certain to grow when root-grafted.

This past spring (1875) I did some grafting with scions and stocks which had stood out all winter and had been exposed to a temperature of 26° below zero. After the ground thawed I took up the Plum stocks and whip-grafted them with Peach and Plum scions just cut from the trees. They were then put in the cellar until it was safe to plant them out. Nearly all made a good growth, particularly the Peaches and Plums.—THEO. WILLIAMS, Nebraska.—(*American Prairie Farmer*.)

NOTES ON VILLA AND SUBURBAN GARDENING.

BEDDING PLANTS.—With the month of February comes a necessity for greater activity among the stock of bedding plants, and preparations must be made for potting off the stock of old plants that have been kept in close quarters since autumn. Where several cuttings have been inserted in a pot or box together it is not well that they make many fresh roots before being potted, as the process of separation mutilates them so much that they do not become speedily re-established. After potting afford the plants an increase of temperature, and when doing well remove them to a cooler structure, which will make room for others from the stores.

It will be necessary to increase the stock of many plants by striking cuttings, and for this purpose the plants must be placed in a genial temperature to induce their free and healthy growth. In inserting cuttings special care is needful that they are perfectly free from aphides, thrips, or other insects; for it is astonishing how soon the young growth becomes infested, and fumigation must be a frequent operation, with a moist atmosphere, to prevent the inroads of red spider.

If there is no regular propagating place a dung bed must be made up, and a frame placed upon it. If a bottom heat of 60° can be secured, it will be sufficient for the pots to be plunged in. As a plunging medium some use sawdust, others old dried tan, while a bed of leaves, if they are packed closely round the pots, will answer well.

The cuttings must be inserted as they can be had, for it is not always possible to secure a very large batch at the same time; they must be well fastened in the soil and must not be moved until they are rooted. A good plan of procedure is to well drain some small pots and fill them to within an inch of the top, pressing the soil down moderately firmly, and over this place about an inch of silver sand, watering with a very fine rose until the sand begins to throw the water off. The moment the water has passed through the sand and has soaked away, the cuttings should be inserted, using no stick to make holes with, but pressing in the stem of each cutting with the thumb and finger, which is an easy matter as the sand is soft. The pots when filled should be gently watered, and the settling of the particles of sand will fasten the cuttings. As soon as the pots have drained off they may be placed in the frame.

When the cuttings start into growth after rooting, pinch out their points, which will, in turn, make cuttings if required. As soon as roots are emitted the young plants should be removed to a cooler temperature, and when side shoots spring out the plants may be divided and potted, and grown-on for a time, then gradually hardened off into cool frames. In the case of small plants such as Verbenas, one pot will root from thirty to fifty cuttings.

There is no occasion to trim the cuttings to a joint, but where this is not done care must be taken that the first joint next above the foot of the cutting touches the surface, for although the stem will emit roots, the principal roots will come from the joint.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

The fruit buds do not seem to be very prominent on either Apple or Pear trees in the open garden, and there is every appearance of a late blossoming season. There is not much required amongst the trees at present, the ground between them had a coating of manure a few weeks ago, which is now being lightly forked-in. The Raspberry quarter is receiving the same treatment. Some persons would recommend not to dig-in the manure at all, but allow it to lay on the surface all through the summer months. Both plans have been tried here, but forking the ground over meets with the greatest approval. It has neatness in its favour, and the trees seem to thrive quite as well one way as the other. If the weather sets in very hot and dry next summer, and it becomes necessary to water the trees, then a mulching of half-rotted manure applied to the surface and left on would arrest evaporation, and be productive of good results.

Pruning and nailing the trees on walls should be forwarded without any delay, leaving Peach and Nectarine trees to the last. Planting should be finished as expeditiously as possible. The trees should be even more carefully lifted at this season than in the autumn, saving all the fibrous roots, and the ground should be ready for them as soon as they arrive from the nursery.

We shall run the hoe through the ground between the rows of Strawberry plants in the open quarters, for the seeds of weeds are introduced amongst the loam used in planting, even if the ground is otherwise free from them.

VINERIES.

We are cleaning and otherwise preparing the late houses for the starting of the Vines. We have out a good many bunches before pruning and hung them up in the fruit-room with the ends of the laterals in water. Upon the whole the late Grapes with us are not keeping nearly so well as usual; even with Lady Downe's Seedling some of the footstalks of the berries have decayed, and other sorts have shrank badly. We have been truly glad of an hour or two of sunshine on several days last week, the effect of it seems to be already visible on the early Vines; it allowed the ventilators to be opened a little more, which must add strength to the young and tender shoots.

Those who desire to have ripe Grapes about the end of April will now be thinning-out the berries. Many persons do this at twice, a portion now and the remainder just before the stoning period. This is not good gardening, the gardener who is up to his work will know at what size the berries will swell, and remove all that is required at the first thinning. The berries should be thinned-out at the earliest stage possible. We usually begin to thin about nine or ten days from the time the first flowers open.

If the eyes intended to produce fruiting canes this year are not yet put in heat, the sooner this is done the better. A bottom heat of 86° with a temperature of 55° for the atmosphere of the house, is the most suitable. The pots should not be watered from the time they are placed in heat until the Vines are above ground. If the soil becomes so dry that it is necessary to water them, it is very probable that many will not start at all.

PEACH HOUSE.

We alluded on the last occasion to trees in blossom, and urged the importance of setting the fruit by artificial means, shaking the branches and dusting the pollen from the anthers to the stigma of the best flowers on some of the shoots. Disbudding must now be proceeded with; a very large proportion of the young shoots may be rubbed off, leaving one near the base of the last year wood, training one for a leader and another on the opposite side to the one selected near the base. The fruit may also be thinned-out, leaving the largest equally placed over the trees.

As soon as the fruit is all set the syringing of the trees that was necessarily suspended during the flowering period should now be continued vigorously. Rain water that has been in pots standing on the hot-water pipes should be used. The Peach trees do not suffer so much from draughts of cold air as Vines, but it is far the best not to subject the trees to this influence. Late houses are very useful for bedding plants, and as much air may be admitted as possible to keep the trees back until it is time to remove the plants to temporary shelters out of doors.

MUSHROOM HOUSE.

It is not worth while to say anything about the making-up of the beds, as this was fully entered into at the end of last year. We would urge the importance of a fair degree of moisture in the beds before spawning, and also allowing the beds to cool down before inserting the spawn. The heat of the bed should

not be more than 85°; the spawn is often injured by too much, but seldom by too little heat. Some clean straw placed on the surface helps greatly to maintain an equable temperature. A moderately-moist atmosphere with a temperature of 55° is most congenial to the Mushrooms. It ought also to be noted that a dry atmosphere causes the produce to be leathery in texture.

CUCUMBER HOUSE.

It was here stated that Cucumber seeds were sown in the last week of December, and that the plants were potted three weeks after in small pots. They have again been repotted into larger pots and placed quite near the glass in a night temperature of 65°. It is better to grow the plants on like this than it is to plant them out before they are strong. We shall grow them on in pots until the plants are about 18 inches in height. It is of the greatest importance to keep them free from insect pests. Thrips and green fly are easily destroyed by fumigation, red spider by syringing. The plants will grow slowly for a few weeks, but we promote growth as much as possible by shutting up at 2 p.m., and as the days have been bright the temperature is up to 75° or 80° for several hours afterwards.

GREENHOUSE AND CONSERVATORY.

It is scarcely possible to grow hardwooded plants well in a house that has to be used as a show house for forced plants from Christmas or earlier until May. Plants that are removed from a forcing house to one where air is so freely admitted as it ought to be where hardwooded plants are grown would suffer by the sudden change; to restrict the injury the house may be kept closer for a day or two, but in a few days more fresh plants are brought in and it is necessary to frequently close the ventilators when they ought to be open for the more hardy plants. The heating apparatus is also very much oftener in use than it ought to be. It is not necessary to apply heat for a degree or two of frost, especially if the house was shut up with sun heat. We would rather see the thermometer down at 35° than up at 45° on a cold night.

Cinerarias are making good growth now, the plants must on no account suffer for want of water, nor the least trace of green fly or thrips be allowed upon the leaves. The Cineraria is a comparatively hardy plant, but it must not be subjected to a temperature below 35°. We had a number of plants much injured with the thermometer at 38°, the plants were closer to the glass than the thermometer, and were, no doubt, in a still lower temperature.

We shall in the course of a week or ten days report the stage *Pelargonium*. These plants are very often over-potted. A plant that will produce a dozen nice trusses of flowers in a 5-inch pot, would run more to leaf in a 6-inch pot and might not give half so many flowers. A pot 6 inches in diameter is large enough for a good-sized plant, and one 8 inches will do for the largest. We use good clayey loam, one-fifth of rotted cow manure, leaf mould in the same proportion, and enough white sand to keep the compost porous. It is not easy to say how much sand, as some loams are much more sandy than others. Drain the pots well, placing some tough fibre, from which the clayey portion has been shaken out, over the drainage.

Hardwooded plants may also be repotted if they require it. Good, tough, fibrous peat is the staple material for nearly the whole of them; it must not be sour stuff obtained from marsh land, but the top spit from upland moor or pasture, that containing sharp white sand naturally is the best. The potting of hardwooded plants must be much more carefully performed than that of softwooded plants. The pots must be quite clean and well drained, and what is sometimes neglected, the drainage must be kept clear by placing some fibre carefully over it before putting in any of the compost. Pure sandy peat is essential for Heath, Epacris, Azalea, Lapageria, Rhododendrons, Dracophyllums, and Dillwynias. Most other plants require turfy loam in the proportion of one-third.

The state of the roots should be a guide as to the size of pots to be used. If the plants are well rooted and of robust growth they may have a shift of 2 inches; if the roots are in bad order it may be necessary to reduce the ball and repot in the same sized pot, or one even smaller than that in which the plant was growing before. The roots ought to be moderately moist before turning the plants out. The compost to be used should be the same, a very dry compost is about equally injurious to one over-moist. The plants must be potted firmly, if the compost is not rammed in pretty tight when the plant is watered the water passes through it without moistening the ball. It is better at this season not to apply any water to hardwooded plants for a week or ten days after repotting.

Some plants may be placed in heat with advantage. *Statice Holfordii* and *Pleroma elegans* does well in a temperature of 50° or 55° at night.

We shall put in cuttings of the *Perpetual-flowering Carnations* this week; they strike well in a frame with a little bottom heat. The very small side-growths are the best. About a dozen of them may be inserted in a 5-inch pot; the soil should be equal parts of loam and leaf-mould with a little sand mixed with it; a layer of sharp sand should also be placed on the surface of

the pot. Some varieties strike roots much sooner than others; the Perpetual-flowering Plootees, Prince of Orange, and Asot Yellow are the most difficult. We generally propagate them from layers. It is necessary to put in the cuttings of these useful Carnations thus early, so that the plants may be of large flowering size before they are taken into the house for the winter.—J. DOUGLAS.

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

BRIEFOL (Spring Show). March 22nd and 23rd. Mr. G. Webley, Holm Wood, Westbury-upon-Trym, Hon. Sec.

ROYAL CALDERIAN HORTICULTURAL SOCIETY. Shows April 5th, July 5th, and September 15th.

WESTMINSTER AQUARIUM. April 12th and 13th, May 10th and 11th, May 20th and 21st, July 5th and 6th, October 4th and 5th.

SOUTHAMPTON. June 5th, and August 5th and 7th. Mr. C. S. Fudge, 62, York Street, Sec.

MAIDSTONE (Roses). June 21st. Mr. Hubert Bensted, Rockstow, Maidstone, Sec.

SPALDING. June 21st. Mr. G. Kingston, Sec.

RICHMOND. June 29th. Mr. A. Chancellor, Hon. Sec.

SOUTHPORT. July 6th, 7th, and 8th. Mr. E. Martin, Sec.

HELENBURGH (Roses). July 12th and 13th. Mr. J. Mitchell, Sec.

BRIGHTON. July 29th. Messrs. C. Jessop & E. Rawnsley, Hon. Secs.

SHARON BURN. August 26th. Mr. B. Richardson and Mr. W. Elliott, Secs.

DUNDREN (International). September 7th, 8th, and 9th. Mr. W. R. McKelvie, 35, Enfield Crescent, Sec.

TRADE CATALOGUES RECEIVED.

John Laing, Stanstead Park Nurseries, Forest Hill, London, S.E.—*Catalogue of Garden, Flower, and Farm Seeds, Implements, &c.*

Wood & Ingram, Huntingdon.—*Select List of Garden and Agricultural Seeds.*

Little & Ballantyne, Carlisle.—*Illustrated Spring Seed Guide and General Catalogue.*

Brunning & Co., The Nurseries, Great Yarmouth.—*Illustrated Seed Catalogue with Select List of Gladioli.*

Stuart & Mein, Kelso.—*Illustrated Catalogue of Seeds and Roots, and Select List of Gladioli.*

Richard Bradley & Sons, Halam, near Southwell, Notts.—*Catalogues of Roses and General Nursery Stock.*

David Gold McKay, Market Hill, Sudbury, Suffolk.—*Catalogue of Seeds, Gladioli, and Garden Requisites.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

OVERCHARGE FOR THIS JOURNAL (W. F.).—Your bookseller was wrong. No extra charge was made by us for the Title and Index.

BOOK OF FLORICULTURE (T. L. B.).—There is no standard work on floriculture, giving detailed and precise instructions. Such a work would require to be extremely voluminous, and be too costly for the acceptance of horticulturists generally. Our "Florists' Flowers," 5d.; "Indoor and Outdoor Gardening," 1s. 7d. each; "Greenhouse Manual," 10d., and the "Cottage Gardener's Dictionary," 7s. 2d., would give you all the information required. They may be had free by post from our office at the prices named.

FELTON PARK (Miss A.).—Near Acklington, Northumberland.

EXAMINATION OF GARDENERS (J. A. S.).—We are informed that there will be no examination this year by the Royal Horticultural Society.

PEAR SCIONS ON APPLE STOCKS (W. Sanders).—Pear scions will unite to Paradise Apple stocks, but they will not live.

GARDEN PLANS (Alpha).—We know of no work for your purpose. There are very many plans in our back volumes which you could draw from, and learn there how they were effectively planted.

HOLLY HEDGE (H. K. L.).—You ask what distance apart should the "trees" be planted? The question must be decided entirely by their size. We have planted them when small at 6 inches apart, and when larger at 2 feet distances, and the hedges now are equally good. Loosen the soil well and plant so that the foliage of one "tree" touches that of the other without any crowding or pressing. To insure uniformity of growth we should plant solely the common green Holly, on which when the hedge has attained nearly its full size, variegated sorts may be grafted at intervals for ornamental effect.

STOVE AND GREENHOUSE ARRANGEMENT (E. H. D.).—We presume you have a duplicate copy of the queries you have submitted. No. 1, Yes. 2, Have 4-inch pipes. 3, Add a foot of tan or fermenting manure and leaves, and on this place a foot of soil for Cucumbers. For plunging plants use tan or

coco-nut fibre. 4, Ample for the greenhouse. 5, It is much preferable. 6, If the coke supply is constant a tubular; if not, a saddle. 7, Yes, it will do very well. On the point of piping arrangement and other practical matters you would find the advice of a neighbouring gardener valuable. Invite a man of ability to half an hour's discussion on the spot. In fixing hot-water pipes the flow-pipe should be taken from the top of the boiler and rise gradually to the highest point, and then return with an easy decline to the bottom of the boiler, the pipes in no part sinking below the bottom of the boiler. At the highest point in the piping insert an air-pipe, and the boiler feed system should be level with the highest part of the piping, the pipe from the eastern entering the boiler at the bottom, or, which is often more convenient, entering the return-pipe close to the boiler.

DESTROYING AMERICAN BLIGHT (T. Hogg).—This destructive pest is not a bug, but an aphid—viz., *Aphis lanigera*. It is best prevented and destroyed by dressing the trees infested with paraffin oil, applying with a brush, more particularly to the excrescences caused by the aphid in the bark, brushing it well into those parts and the angles and crevices. It is best done in March, or before the buds commence growing, but may be applied during growth to the parts attacked, keeping from the foliage.

BLUE LOBELIA (J. P.).—There is no better than a good strain of *Lobelia speciosa*; we find nothing better than Vetch's strain, Crystal Palace compacta being very good. Last season was a very unfavourable one for *Lobelia*.

HARDINESS OF CRYPTOMERIA ELEGANS (Idem).—It has stood unharmed in a high and exposed situation several winters, and would no doubt succeed as a specimen tree in a park, but would need to be fenced against cattle, and made proof against hares and rabbits, the hares leaping with us netting 80 inches high. Upon the spray of the *Cryptomeria* they feed greedily. It is a very graceful tree of deep chocolate tint.

REPORTING HOLLIES (W. Berry).—Turn the plants out of the pots at the close of March, and remove with a pointed stick all the soil that can be picked out from the roots without injuring the fibres; if the soil be in a sodden state and the roots few remove all the soil, and in reporting work the soil in amongst and between the roots, not crowding them together, but spreading evenly through the soil, keeping the settling-on of the roots or the neck of the plants level with the rim of the pots, potting moderately firmly, leaving space below the rim for watering of about an inch. Good drainage should be provided, and a compost of rather strong fibrous loam, with a fourth of well-rotted manure, will grow them well. Plunge in ashes in a slightly shaded situation, sprinkling overhead twice a day in dry weather until they are growing freely, but do not water at the roots more than to keep the soil moist, and when established remove to an open situation, watering freely as the growth progresses, and always keeping moist.

POTTING CAMELLIAS (T. L. B.).—It may be done directly after the flowering period, or before fresh growth is made, and any pruning required should be done at the same time. If the pruning be at all free the plants will need to be placed in moist heat to secure their breaking freely. The potting may also be performed in late August or early September, the buds being then well formed. We usually prefer the latter time for potting, the roots being in a healthy state; but if much removal of soil is necessary, the roots being in a bad state, spring potting is preferable, encouraging root-action by a briar moist heat.

DR. DENNY'S AND MR. GEORGE'S NEW PALAEMONIUMS (Idem).—They have been sent out by different nurserymen, and we cannot advise you other than to consult our advertising columns, where they will be announced in due course.

PLANT GRANDIFLORUS CULTURE (W. D. A.).—After flowering the plants will start into growth, and require the soil to be kept moist, and at no time very dry, though considerably drier when at rest than when growing, when it should be freely watered. They require moderate pot-room and a compost of equal parts of fibrous loam and brown sandy peat, with a fourth part of old dry cow dung, using the soil rather rough. The old pseudobulbs are of no use for flowering, but so long as they remain fresh should not be removed. Repot after flowering. The growth of this year will, if well matured, flower the ensuing winter or spring.

LIBONIA FLORIBUNDA NOT FLOWERING (Idem).—You grow in too high and moist an atmosphere, the plant being kept constantly growing. We grow ours in a greenhouse in a light airy position, the plants being now far advanced for flowering. *Justicia speciosa* does not flower because the plants are grown in too high a temperature and have not sufficient light and air. *Gesnera sebrina* will succeed admirably in a cool stove having a slight shade and moist atmosphere during growth.

PLANTING VINES (O. W. Milne).—Plant in March, turning them out of the pots, disentangling the roots and spreading them out evenly over the border, and covering with from 4 to 6 inches of soil. Black Hamburg, Foster's White Seedling, and Vann's Black Muscat will suit you.

PRUNING OUTDOOR VINE (S. R.).—We should not cut the Vine back more than to remove any unripened growth, and should train the cane horizontally at a foot distance from the ground, and when the eyes are broken and a few inches long rub off all the shoots on the under side and front, leaving a shoot at every 18 inches distance, every second of which is to be trained upright and to the top of the wall without stopping, then take out the point of each, stopping the laterals at the first joint, and do that throughout the season. The first shoot taken to the top of the wall or retained for that purpose should be 18 inches from the end of the wall, from whence the Vine starts, and the next that is to be taken up the wall feet distance from it, and so on. A shoot should be taken from the end of the Vine, training it upward, or nearly so, and in the autumn following it may be brought down to the horizontal position, and shoots originated from it as upon the other of a previous year's growth. In this way you will originate the rods for covering the wall, and from which you will in due course have shoots for bearing. The shoots between the principal canes should be stopped at the sixth leaf if they do not show fruit, and, if fruiting, at one joint beyond the bunch, and the laterals to one leaf.

PHACIA, NECTARINE, AND APRICOT TREES FUNGUS (A New Beginner).—The mould or parasitic fungus upon the shoots of the potted trees where the leaves were situated is a result of damp, and we do not think in anywise injurious to the trees. It will, if it be what we suspect, disappear upon a good syringing, which should not, however, be given before March, or until the buds commence swelling. We should dress the trees with a mixture of 4 ozs. of soft soap to a gallon of tobacco juice, brought to the consistency of thin paint by the addition of flowers of sulphur, applying with a brush to every part at once, taking care not to dislocate the buds. It is good against insects, and will not injure the trees if it be done carefully, the brush being

drawn upward, and not downward where the buds are situated. Do it before the buds swell.

DIONCA MUSCIPULA CULTURE (J. S. S. B.).—The plants are dead if they have antihy disappeared, but you may try them by potting in rough peaty soil and a fourth each of sphagnum and crocks broken small, draining one-third the depth of the pot and standing in a saucer stuffed round lightly with fresh moss and kept full of water, covering the plant with a bell-glass, but raised a little by a thin piece of wood, placing near the glass, but with a north aspect, or with plenty of light, but protected from bright sun. A 4-inch pot will be sufficiently large. 50° at night to 65° by day is a suitable temperature, or a warm greenhouse.

VINERY HEATING (C.).—The aspect is not a good one, but if there is not shade or objects that will obstruct the light there is no objection to it other than that you will have to make up for a deficiency of natural heat by artificial. Almost any kind of Vines would answer, but we could not advise as you do not say whether the vinery is intended for early, mid-season, or late. A 4-foot border and all inside will be practically useless after two years. There should be a width of border equal to that of the house, and half of it outside. The bottom of the border being rocky there may be no need of drainage, which can only be determined on the spot. There is no objection to the depth of the border; and as to the ingredients of which the border is to be composed, we do know good Grapes have been grown in such stuff, but it is a very poor one, and would require very high feeding in the shape of liquid manure. No one in these advanced days would think of such a border. An orchard house in "a regular shaded corner" will be certain to give a plentiful crop of disappointment, and only that; and you seem quite as unhappy in the selection of a slow-combustion boiler, though if it be a large size, and of ample heating power, there is no objection. The whole appears to us to be ill devised—not well adapted for the purposes intended, but there may be reasons which prevent its being otherwise, on which we can offer no opinion.

PLANTING STRAWBERRIES (F. M. S.).—You may safely remove the young plants which were planted in September, selecting favourable weather in February for the operation, taking up the plants with good balls of earth attached to their roots, and planting them carefully in good soil. Do not plant too deeply. They will require no special protection.

JERUSALEM ARTICOKES (Idem).—Tubers planted any time in February will produce a crop in the autumn the same as Potatoes. They are best in a single row, planting a foot apart; if in a bed the rows should be 8 feet distant from each other. Thinning of the stems is seldom necessary, but if more than one proceed from a root, draw them out when a few inches high. You will find what you need on the cultivation of Horse-radish in another column.

HEATING A CONSERVATORY (J. H.).—Providing the greenhouse boiler is sufficiently powerful to heat the 80 yards of flow and return piping necessary to connect it with the conservatory piping and the piping that will be required to heat the latter, there is no objection, but there will be a loss of heat from the 80 yards of connecting pipes which should be taken in a covered flue, and being open at the conservatory end some of the heat will be utilised for heating the conservatory. To heat the 2000 cubic feet of air you will require about 190 feet of 4-inch piping.

COCOA-NUT FIBRE REFUSE FOR HOTBEDS (J. Long).—It is not a fermenting material, and therefore it is practically useless for affording heat to a hotbed. It is valuable as a plunging material, and in its decomposed state a desirable compost for plants.

NITRATE OF SODA (A New Beginner).—The following is all the information we can render you:—Nitrates of potash (saltpetre) and of soda (sulfate potrie) have been found beneficial to Carrots, Cabbages, and lawns. One pound to a square rod of ground is a sufficient quantity. Both these nitrates have been found beneficial to Potatoes in Scotland. Mr. Murray says that from 1810 down to the present time he has been in the habit of watering Potatoes and Carnations with solutions of these two nitrates, and the benefit has been uniform and eminent in promoting their luxuriance. They have also been given in solution with great benefit to Chrysanthemums, Lettuces, Celery, Fuchsias, and Dahlias; 1 lb. to twelve gallons of water. Nitrate of soda destroys slugs.

NAMES OF FRUITS (J. Elliot).—We do not recognise the Apple. It is pleasantly flavoured, but the flesh is rather tough.

NAMES OF PLANTS (A Subscriber, Cheshire).—We cannot name plants from a leaf only, we need a flower also. (*W. F. E.*)—*Ixora coccinea*. (*W. C. E.*)—We regret that your flower had so shrivelled before reaching us as to be quite undeterminable.

POULTRY, BEE, AND PIGEON CHRONICLE.

SILKIES.

By REGINALD S. S. WOODGATE.

PART 2.

SILKIES for exhibition should be crested, 5-toed, leg-feathered, mulberry-combed, pure white in colour, light blue in ears, and legs and beak of a dark bluish slate colour. They should not be vulture-hooked: we consider this a great blemish, and would immediately destroy all birds with the slightest appearance of it. The toes should be as much as possible like the Dorking's, for the fourth and the fifth toes growing out of each other are a great blemish. The comb should be dark and mulberry-shaped; it should be smooth and fine in texture, and not rough. Our idea of a perfect comb for a Silky cock is that on the cockerel of the first-prize Alexandra Palace pair, which were claimed there for the large sum of £10, which is an extraordinary price for birds of this breed so little cultivated for exhibition purposes. The comb is slightly hollow in the centre, but this for a Silky comb is rather a point than a defect. The crests should be large, in the pullets almost hiding the combs, and they should be globular and compact, not like the crest of a cockateo. The leg-feathering should be distinct and go all down the legs to the

middle toe; but heavy feathering is not desirable or pretty—all that is wanted is a narrow margin or edging of feathering down the legs. The earlobes should be turquoise blue in colour: this is much more easily obtained in the pullets than in the cockerels. In the latter it generally comes streaked with white. We have, however, seen perfectly blue lobes in cockerels as vivid in colour as in any pullets. In the second year in both sexes, however, the colour is apt to fade and the lobes to come almost white: this is very ugly, and would prevent, or should prevent, a bird winning in strong competition. To remedy this many do not try for the blue ears at all, but breed from and for the dark raisin-coloured-faced birds, which generally keep their colour for some seasons. Silkies, however, are not of much use for exhibition after their first year, for the leg-feathering rarely comes heavy again in the second moult, especially in the hens. Of course it does sometimes, but we find it is the exception. Young birds should not be discarded for being buff or pink in breast, for very often—in fact generally—it will moult out except in very bad cases. We should never, however, breed from such birds where we could help it.

A perfect pair of Silkies for exhibition, in our opinion, should be rather small, but not too small, round in shape and very fluffy and silky, especially on the thighs and breast. They should have hardly any tails, and no hard feathers in either tails or wings. They should be low on the legs, and possess all the other desired points as named above. We hardly think the breed has justice done to it in the show pen, for it generally has to appear in the Variety class, and in that unhappy refuge the denizens are so varied and various that it must be almost a lottery which wins, the judge's whims and fancies being necessarily brought to bear. Still, all adjudicators should remember that it really is as difficult a matter to breed a perfect pen of Silkies as it is anything else. When we say perfect we know there are annually but few such pens extant; still most of those have to "come out" in the Any other variety class.

In mating them for breeding we like a cockerel and two-year hens best, but we in any way breed generally from a cockerel. We look for distinctness in toes, compact shape of body, combs and crest, before mere whiteness or leg-feathering. The latter with judicious crossing can nearly always be obtained; but the good claws and size of crest are very difficult to procure and only a few strains possess these merits. We never breed from a vry-tailed cock if we can avoid it, as this is wont to get worse and worse as years go on; in fact we know of one yard where the tails are thought nothing of, and many of the birds before their *début* in the show pen have Hamburg-like stables, but when prepared for the glories of the exhibition room they are made to undergo the Bo-peep penalty and leave their tails behind them. This often happens, too, in the case of hooks, for during the past season many of the Silkies have been as much plucked in their hooks as Brahmas or Cochins. This latter evil we lay entirely at the judges' doors, for if they will insist on such an absurd amount of leg-feather they must expect hooks. We do not for an instant wish to be thought to object to leg-feathering—very far indeed from it, but only a narrow strip or edging down the legs is needed or desirable for beauty in our opinion. A perfect Silky feather is a most beautiful thing. We have often had letters from ladies, who have seen our birds at the shows, writing to beg us to sell them the feathers by the ounce for fancy-work in swans and such like. A very admirable illustration of Silky feathers, one in the natural state and one magnified, are to be found in the chapter on Silkies in the "Illustrated Book of Poultry." The feather which is not magnified is a perfect representation of what the feathers should be in the fluff of good specimens.

To hatch for exhibition the time must depend upon the month when they are wanted for. A bird rarely gets perfect in points until it is five or six months old, and some late-hatched birds do not thoroughly get their matured plumage till the second year; still, generally, birds hatched in May and June will be quite ready for the Palace and Oxford Shows, at both of which places they have classes. Sometimes they are for some weeks, when about four months old, quite yellow on the breast and wings. This colour, however, is in no way similar to the buff or pink which we have mentioned before, but resembles feathers dipped in the yolk of an egg. This is merely the sap in the feathers, and will generally come quite right. We have seen birds almost lemon-coloured from this which have in time come snow-white, but we believe it to be more common to some strains than others. Still, no bird should be too soon discarded for this peculiarity.

Silkies are good and rough feeders. Nothing comes amiss. They eat everything greedily which a fowl can eat, but we never give maize, believing it tends to making the plumage yellow. Silkies, like all other white birds, are liable to being sunburnt; but this again we believe is more in some strains than in others. Birds for exhibition should, however, be kept in the shade, where they can have the shelter of living shrubs and underwood, and then they will rarely change colour. It is more often seen in the cocks than in the hens, though we have observed at

shows and elsewhere the latter almost golden in neck hackles from being kept in an open and exposed place where there was no shelter from the winds or sun.

CUTTING THE COMBS OF COCKS.

At the Sittingbourne Petty Sessions Charles Sayer, landlord of a public-house at Rainham near Sittingbourne, and John Manning, veterinary surgeon of Rochester, appeared in answer to summonses issued at the instance of the Royal Society for the Prevention of Cruelty to Animals for having unlawfully ill-treated three Bantam cocks by cutting their combs. The only question was whether the operation of cutting the combs of cocks is cruel.—Mr. James Broad, a member of the Council of the Royal College of Veterinary Surgeons, stated on oath that the practice of "dubbing," or cutting the combs of cocks, inflicted great pain upon the birds, and they were not benefited or improved by the operation. Several nerves must be severed in the operation. Indeed, he said the comb of a cock was the most vascular part of the whole body.—Mr. William Henry Jones, M.R.C.V.S., gave corroborative evidence.—Mr. Frederick Crook, one of the editors of *Land and Water*, and one of the principal judges at the Crystal Palace Poultry Shows, deposed that it was very detrimental to birds to cut their combs. He discouraged the practice as much as possible; he wrote against it, and it was he who suggested to the Baroness Burdett-Coutts to offer prizes for "undubbed" birds. He would like to make it a *sine quâ non* in all poultry shows that the birds should not have their combs cut.—Mr. Harrison Weir, the well-known animal painter, was then called, and he gave it as his decided opinion that the practice of cutting the combs of cocks caused them great pain, and spoiled their appearance.

The magistrates, after consulting in private, dismissed the summons, the chairman stating that the Bench did not consider that this was an offence within the meaning of the act.—Mr. Smith applied for a case to a higher court and the magistrates granted it.

WOLVERHAMPTON SHOW OF POULTRY, &c.

HAD the Show not included a Sunday the entries would have most probably been heavier, for as it was many of the classes were but lightly filled. In *Game* the cup went to a fine old Black Red cock, good in shape and head, and grand in carriage. Mr. Mathew walked off with the lion's share of the booty, but his birds were so hard in feather and glossy from good condition, and to win in *Game* these points must be observed. In *Malays* we thought the winners well placed. Of *Brahmas* the first hen was a beauty, and exquisitely marked. The cup went to a cockerel, large in body and good in colour. The first hen and first pullet must, however, have run him close for the cup. A very lovely pullet, large and good in hackles, won the cup in *Lights*. The first Light cockerel was a well-standing bird, and large in body. We certainly thought, taking class by class, the Lights on this occasion surpassed their Dark relatives. *Dorkings* were good as far as they went, but did not come in the numbers they should have done. The cup went to old Coloured, a nice pen, where the hen was large and good in colour. Of *Silver-Greys* every pen noticed. In *Whites* the first hen was a very good one, square and large. Of *Cuckos* the three pens all belonged to one exhibitor. We cannot discern why this variety has not more admirers if, as we believe, they are great layers. *Cochins* were simply grand, all colours equally good. The cup went to fine old Buffs, lots of pens, however, pressing on them for cup honours, but we liked the award. Buff pullets were remarkable for good colour, and Partridges for pencilling. We liked the winning cockerels very much of this latter colour, and have watched their owner with interest advancing until he here has reached the top. Whites were very fine, and there was really scarcely anything to choose between the third-prize and the very highly commended pens. Perhaps the latter was as good as the second or third. Blacks were capital, and we hail the first-prize owner's arrival with pleasure. Mr. Darby's bird was splendid. *Houdans* were very few, and *Oréves* were also good in quality. Of *Spanish* after the winners we noticed nothing remarkable. The winning hens were good in face, and nicely shown. *Polands* were very good; most splendid *Silvers* first, grand *Gold* second, and admirable *Blacks* third, with huge crests. *Hamburgs* made a nice display. The winning *Gold-pencils* were very good, and the pullet beautifully pencilled. The first *Gold-spangled* cock was a grand bird, and in fine order. *Game Bantams* were good, and in the *Variety* class a pen of excellent *Blacks* were first. In the *Variety* class *Indian Jungs* were first, *Black Hamburgs* second, good in style and colour, and *Cuckoo Cochins* third, good *Silks*, *La Flèche*, and more *Black Hamburgs* being highly commended. The *Sale* classes were large. Some of the birds were good, but sale classes are not what they used to be for bargains; and become now more of a lottery, as a kind of *fiacre* to a show. *Aylesburies* were good, but *Bouens* still better; the winning pens of *Rouens* being

first class, good in colour and very large. In the *Variety Duck* class every pen nearly was worthy of note. The rare *Paradise Shield Drakes* of Mr. Serjeantson were first, and secured much admiration. Mr. Brown had a very lustrous and good pair of *Blacks*, which we should have liked to have found a place for in the prize list.

The *Pigeons* were very fair in quality. Mr. Yardley's *Carriers* and Mr. Pratt's *Pouters* were all good birds and well shown. We liked the first cock in *Pouters* very much. He was long in limb and good in colour. A good *Red Chequer* won in *Antwerps*—a useful-looking and well-made bird, and a nice *Dun* second. Of the *Fantails* the three winners were perfect gems. Mr. Serjeantson's first was a beauty for tail, and in spotless feather. The *Turbits* were moderate—a neat *Red* second. The *Yellow* was also a good one. In the *Variety* class were good *Blondinettes*, a *Fire Pigeon*, and some fair *Maggies*.

GAME.—*Black Red.*—Cockerels.—1, S. Mathew, Sharnbrook. 2, J. Palmer, Wednesbury. 3, G. Walters, Worcester. *Brown Red.*—Cockerels.—1 and 2, S. Mathew. 3, Capt. J. Forsyth, Tottenham. *Excepting Brown and Black Reds.*—Cockerels.—1, S. Mathew. 2, D. Hulme, Alresford. 3, D. Huxley, Birmingham. *Any variety.*—Cock.—Cup and 1, S. Mathew. 2, W. & H. Adams, Beverley. 3, D. Hartley, Hen. 1, T. Mathew. 2 and 3, J. Forsyth, Malvern. 1, Miss A. Brooke, Sharnbrook. 2, G. S. Smith, Bagley. 3, J. Hinton, Warrington. *Brahmas.*—*Dark.*—Cock.—1, Hon. Miss Douglas Pennington, Penryn Castle. 2, T. F. Ansell, Rev. A. Van Straubenzee, Tottenhall Vicarage. Hen.—1, Newham and Manby, Wolverhampton. 2, F. Holbrook. 3, E. Pritchard, Tottenham. *Cockerels.*—Cup, 1, and 2, Horace Lingwood, Cretingham. 3, R. P. Percival, S. J. Lyon. *Pullets.*—1, Newham and Manby. 2, Horace Lingwood. 3, J. Long. 4, J. Biddle, Birmingham. *Light.*—Cock.—1, Horace Lingwood. 2, R. E. Horsfall, S. W. A. T. and Aylsbury. Hen.—1, S. Sanbrook. 2, F. Holbrook. 3, J. Woodworth, Cheltenham. *Cockerels.*—1, P. Haines. 2, R. E. Horsfall. 3, T. A. Dean. 4, W. T. & J. Pullet. Cup and 1, R. E. Horsfall. 2, P. Haines. 3, Horace Lingwood. 4, W. T. & J. Pullet. *Coloured, except Silver-Grey.*—Cup and 1, J. White. 2, J. Coppell. 3, W. Badger. *Silver-Grey.*—1, W. Row, jun., Newark. 2, W. W. Eustidge. 3, Miss Pansey. *White.*—1, A. Darby, Sharnbrook. 2, R. B. Bissler, Birmingham. *Light.*—Cock.—1, G. S. Smith, Bagley. 2, R. E. Horsfall, S. W. A. T. and Aylsbury. Hen.—1, W. A. Burnell. 2, Mrs. A. Tindal. 3, Mrs. A. Tindal. *Buff.*—Cup and 1, W. A. Burnell. 2, Mrs. A. Tindal. 3, Mrs. A. Tindal. *Black.*—Cock.—1, Mrs. A. Tindal. 2, G. S. Shrimpton, Leighton-Buzzard. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Indian Jungs.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Malays.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Indian Jungs.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Malays.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Indian Jungs.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Malays.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Indian Jungs.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Malays.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Indian Jungs.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Malays.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Indian Jungs.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Malays.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Indian Jungs.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Malays.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Indian Jungs.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Malays.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Indian Jungs.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Malays.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Indian Jungs.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Malays.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Indian Jungs.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Malays.*—1, Mrs. A. Tindal. 2, J. B. Woodworth. 3, W. A. Burnell. *Black.*—Cock.—1, R. E. Horsfall. 2, G. S. Smith, Bagley. 3, J. H. Jones. *Pullets.*—1, Mrs. A. Tindal. 2, F. Bennett, Sharnbrook. 3, J. H. Jones. *Indian Jungs.*—1, Mrs. A. Tindal. 2, J. B. bloom and condition. Black Reds had to compete with Duckwings; they won first, however, and good they were. Of *Hamburghs* the Pencilled were the best. A neat pair of Golds won the cup, Silvers being second; while in *Spangles* Gold were first again and Silvers second. Of *Houdans* the cup pen was really a bijou, and we congratulate their owner on possessing them. Mrs. Vallance had a wonderfully good hen, and so, too, was this lady's highly commended pen. In *Creves* we liked the highly commended pen of Mr. Dring's next best to the first-prize pair. The winners were good in colour and fair in size. In the Variety class *Silbies* were first. The cockerel we believe was the same bird as won first at the Alexandra and there claimed; second moderate *Black Hamburghs*, and third good *La Flèche*. *Bantams* were capital, the Game breeds and the Variety class as well. A good pen was, we learn, disqualified for plucking, because their owner was one of those foolish ones who "cannot leave well alone." *Waterfowl* were good, *Aylesburys* being capital and *Rouens* well judged and good in colour. In the Variety class *Carolinas* were first and third, and *Pintails* second. We were pleased to see this class looking up here, for often it has been quite deserted. *Geese* and *Turkeys* were admirable. The Sale classes were moderate, and the winners call for no notice.

Pigeons.—In Carriers a Black of ordinary qualities won. In Pouters a pretty Red was first, and a middling Yellow second. Fantails were very good, and a charming pen of Whites won first. Tumblers and Trumpeters were miserable. Jacobins made a better class, but we venture to advise our Kentish Pigeon friends to get some new blood in their lofts. Homing Antwerps were fair, and in the Variety class a nice pen of Barbs, very fair in head and eyes, were first, and pretty Swallows second. The prize awards were:—

DOVER.—*Coloured*.—1, Cup, and 2, R. Cheeseman. 2, G. W. Greenhill. *Silver-Gray*.—1 and 2, F. Cheeseman. 3, J. Boulding. *White*.—1 and Cup Mrs. W. Stratford. 2, R. A. Bolesier. 3, Major W. Plummer. *Cockins*.—*Buff or Cinnamon*.—1, Cup, and 2, G. Dowker. 3, Mrs. A. Christy. *Any other colour*.—1, R. A. Bolesier. 2, R. S. Clarke. 3, Miss E. Marsh. *Spangles*.—1 and 2, J. Francis. 3, A. Marchant. *Bantams*.—*Dark*.—1 and Cup, Miss E. C. Shuter. 2, W. Jacob. 3, J. K. Lawther. *Light*.—1, Cup, and 2, Capt. W. Saville. 3, Miss Hailes. *Game*.—*Brown Red*.—1, F. Ward. 2 and 3, J. Jeken. *Piles*.—1, Cup, 2, and 3, G. H. Fitz-Herbert. *Any other variety*.—1, G. H. Fitz-Herbert. 2, E. Rice. 3, Harms & Elliott. *Hamburghs*.—*Gold or Silver-pencilled*.—1, B. Norton. 2, J. K. Lawther. 3, J. B. Sister. *Gold or Silver-pencilled*.—1, Cup, and 2, G. Dowker. 3, B. Norton. *Extra*.—1, White. *Houdans*.—1, Cup, and 2, W. Dring. 3, Mrs. Vallance. *Creves*.—*White*.—1, Miss A. Sharp. 2, H. Stephens. 3, F. Lake. *ANY OTHER VARIETY*.—1, H. Stephens. 2, H. H. Stickings. 3, W. Dring. *Bantams*.—*Game*.—1 and 2, W. S. Marsh. 3, F. Ward. *Not Game*.—1, W. White. 2, L. G. Morrell. 3, W. S. Monckton.

DOVER.—*Aylesbury*.—1 and 2, W. Jacob. 3, F. E. Arter. *Rouen*.—1, F. Cheeseman. 2, F. Ward. 3, C. Ratcliffe. *Any other variety*.—1, F. Cheeseman. 2, G. Dowker. 3, L. G. Morrell. *Game*.—1, F. Fitz-Herbert. 2, Mrs. T. Fowler. 3, Mrs. W. Stratford. *Tumblers*.—1, F. Ward. 2, G. Dowker. 3, Mrs. W. Stratford. *SELLING CLASS*.—*Cock*.—1 and Cup, H. Stephens. 2, Capt. W. Saville. 3, W. White. *Hens or Ducks*.—1, Capt. W. Saville. 2, R. Cheeseman. 3, T. Goodwin.

Pontreux.—*Carriers*.—1 and 2, G. H. Nutt. 3, J. Chandler. *Pouters*.—1, 2, and 3, G. H. Nutt. *Fantails*.—1, W. Dring. 2, Master G. E. Dowker. 3, Mrs. Hawley. *Tumblers*.—1 and 3, no awards. 2, H. P. Lancaster. *Trumpeters*.—1, H. A. Reeves. 2 and 3, no awards. *Jacobins*.—1, P. Statham. 2, E. Goodwin. 3, P. P. Lancaster. *Homing Antwerps*.—1, E. Durrant. 2, E. Woodwin. 3, W. S. Marsh. *Any other Variety*.—1, G. H. Nutt. 2, W. Simmonds. 3, E. Ross. *Selling Class*.—1, J. Chandler. 2, M. Sandford. 3, F. Pine, jun.

RABBIT.—*Long-eared*.—1, T. Wood, jun. 2, G. H. Nutt. *Himalayan*.—1, G. W. Greenhill. 2, G. Monckton. *Silky*.—1, G. H. Nutt. 2, H. Barham. 3, G. H. Nutt. *Belgian Hare*.—1, H. Barham. 2, G. H. Robinson. *Any other Variety*.—1, R. A. Bolesier. 2, H. Pankhurst. *Selling Class*.—1 and 2, G. H. Nutt.

JUDGE.—Mr. Teesby.

THE JACOBIN.

I HAVE been so exceedingly busy that I have not had time to notice the remarks of "WILTSHIRE RACTOR" attached to the engraving of a Jacobin of 110 years ago (No. 767, page 521), and after reading them I felt they required some notice from me, especially as I differ widely with him in what he writes. Nor does he, I think, display his usual courteous manner therein when he says, "Old men think what passed in the youth the best, in old age the past is idealised." I am an old fancier, though as yet not such a very old man. And he says further that truth as usual lies in the middle path. I never knew that such was usual, nor do I see how it applies in this case.

He says, "There have been changes in the fancy. The Turbit, for instance, was first plain-headed, then shell-crowned, and lastly, as now, point-headed." For over forty years the proper Turbit had a point head, plain heads were reckoned wrong, and it was only about twenty years ago that the shell head came into vogue, and the point fanciers then contended that they were right, and I am very greatly surprised that "WILTSHIRE RACTOR" should state that the point is new, as I am sure it will provoke more than a smile from all old Turbit fanciers. The Turbits have not varied in this respect during my remembrance, and I am and have been a Turbit fancier. So this does not bear on the Jacobin question.

As regards the English and Foreign Owls, their points are exactly the same, only one is larger than the other. As regards the English Trumpeter, it was precisely the same in every point as the Foreign, rose, turn crown, mottle, feathering of the feet, as the one now called Foreign—no points of difference. I

had Trumpeters that were quite equal to any of the imported birds, in fact rather neater. The feathers on their legs were by measurement 5½ inches, the colour dense black with good mottling. They were never beaten when shown, and their points were just the same as those shown now as Foreign; therefore this does not apply to the Jacobin controversy, for the modern so-called Jacobin does not possess any of the points of the true Jacobin. The true should have hock, chain, and tippet, this last was the part that laid over the shoulders. The things shown now in the Jacobin classes lack all the beautiful curves and grace of the true bird.

"WILTSHIRE RACTOR" also says, "If the minority wish to revive the old type let them offer prizes." This is not at all a courteous way of meeting the question. There is the true Jacobin as the points were laid down, and fanciful judges have thought proper to award prizes to birds not possessing those points, and thereby done the true breed an injury. Let them call the modern things what they like, and have classes for them, but they cannot in justice give them prizes as Jacobins. At Birmingham I have met several old fanciers, and they said that they regretted exceedingly the present style of breed, and one in particular said he was obliged to breed to that style, as certain persons judging would not look at the true Jacobin.

I do not see where the "WILTSHIRE RACTOR's" toleration is when he says "Let them offer prizes, &c." However, to the point. As I find it is the wish of very many fanciers that the bird called a Jacobin should be judged to the true points, I give notice that wherever I act as Judge I shall judge according to the true standard, and I hold that white thighs are a disqualification. Not only shall I so judge, but I am told by more than one of our best judges that it is their intention to do so likewise. I am not at liberty to mention names, but I am very happy to find that they have the spirit to try and remedy an evil arising from bad judging, and judging according to one's fancy instead of rules. I have now written all I mean to on the subject, and I have neither time nor inclination to continue the controversy further, and I quite agree with all Mr. Ure said in his last letter, "There is no comparison between the true Jacobin and the modern thing so called."—HARRISON WAIN.

LONDONDERRY SHOW OF POULTRY, &c.

This was held on the 25th and 26th of January. The awards are as follows:—

BRAHMS.—*Dark-Cock*.—1 and 2, W. G. Mulligan, Belfast. *Hens*.—1 and medal, H. J. McBride, Glifford. 2, W. G. Mulligan. *Light-Cock*.—1, T. A. Bond, Londonderry. 1, E. T. Herdman, Strabane. *Hens*.—1 and 2, T. A. Bond. *Cockins*.—*Cock*.—1 and medal, F. Robertson, Belfast. 2, M. Mahony, Hen. 1 and 2, F. Robertson. *DOVER.*—*Cock*.—1, Rev. W. Major, Moville Rectory. 2, R. E. Herdman. *Hens*.—1, J. Baylow, Castleknock. 2, E. T. Herdman. *Spangles*.—*Cock*.—1 and medal, A. C. Jewell, Derry. 2, W. G. Mulligan. *Hens*.—1 and medal, W. G. Mulligan. 2, J. A. M. F. Smyth, Derry. *FANCY.*—*Cock*.—1, E. T. Herdman (Houdan). 2, F. Watson, Lurgan (La Flèche). *Hens*.—1, E. T. Herdman (Houdan). 2, F. Watson, Lurgan (La Flèche). *HAMBURGH.*—1, E. A. Macdonald, Ballyarnett (Golden-pencilled). 2, Miss L. D. Smyth (Black). *GAME.*—1 and medal, J. Ferguson, Dalmuir. 2, T. H. Graham. *BANTAMS.*—1, Miss L. Stephens, Dublin. 2, L. Stoney, Dublin. *ANY OTHER VARIETY.*—1, J. K. Miles. 2, P. Williams, Cork. *Dark-Cock*.—1, D. Smyth, Dublin (Buff Cuckin). 2, E. A. Macdonald (Coloured Dorking). 3, E. T. Herdman (Light Brahma). *Hens*.—1, D. Sullivan (Light Brahma). 2, W. G. Mulligan. 3, T. A. Bond. *Ducks.*—*Aylesbury*.—1, F. Robertson, Belfast. 2, W. Simpson. *Bouen.*—1 and medal, W. G. Mulligan. 2, W. Simpson. *Any other variety*.—1, Rev. E. A. Brennan, Cloughton. 2, A. H. Stewart, Tuxbury. 3, W. Simpson. 4, H. Lyle, Derry. *Gans.*—1, G. M. Moore, Derry. 2, W. Simpson. *Carriers.*—*Cock or Hen*.—1, D. J. Montgomery. *Pouters.*—1 and 2, J. H. Hutchinson. *Barbs.*—*Cock or Hen*.—1 and 2, W. A. F. Montgomery. *Tumblers.*—*Cock or Hen*.—1, W. A. F. Montgomery. 2, E. R. Lucas. *Jacobins.*—*Cock or Hen*.—1 and 2, J. Pyper. *Fantails.*—*Cock or Hen*.—1, A. Corcoran. 2, M. F. Smyth. *Any other variety*.—1, W. G. Henry. 2, T. A. Bond.

CLAS BUNA.—*Buff or Pale Yellow.*—*Cock or Hen*.—1, M. F. Smyth. 2, W. E. Magill. *Dark Yellow or Orange.*—*Cock or Hen*.—1, C. A. Smyth. 2, E. Rea. *Any other colour or variety.*—*Cock or Hen*.—1, M. F. Smyth. 2, E. Burns. *Young.*—1, M. F. Smyth. 2, A. J. McKinlay. *Males.*—1, W. E. Magill. 2, W. S. Mitchell. *British Birds.*—1, M. F. Smyth. 2, C. Watson. *Foreign Birds.*—*Parrots, Parakeets, Cockatoos, &c.*—1, Mrs. T. A. Bond. 2, J. W. Corbett. *Any other variety.*—1, Mrs. E. Rea. 2, M. F. Smyth.

JUDGES.—O. F. Staunton, Esq.

NATIONAL PERISTERONIC SOCIETY.

THE Society's meeting was held at the Crystal Palace. Of Carriers Mr. Hedley's birds, eighteen in number, were the majority of last year, with long straight-boned beaks, well set. The skull long and flat gave the birds that unmistakable look of high breeding which even the tyro cannot but notice. Mr. Heritage made an excellent display of twenty birds full of condition, with sleek raven feathers and beautiful in the outline that sweeps from the skull to the extremity of the wings and tail—the line of beauty for the artist. Mr. Hodgson showed two good birds, but we missed the Blacks, the Duns, and the Blues of an old enthusiastic member, Mr. Ord, whom we regret to say illness detained at home. The Carriers of Mr. Keeler, especially a young Black hen, we much admired. Mr. Feltham as usual made a good display, as did Mr. Pratt. Mr. Crisp afforded us the treat of a pen of Whites; one hen was remarkably good. He will persevere, we hope, and fill up a gap in our Carrier classes. He also exhibited Duns, Blacks, and some good Blues.

Mr. Cucksey, a young member of the Society, has already made his mark. A matured Black cock was a magnificent bird. Mr. Squaw sent four birds sustaining the reputation of the Plymouth strain. This gentleman's birds are never absent from these annual grand shows, and always delight fanciers. Col. Hassard's birds were, as usual, good; we especially looked on some young Blues and Silvers, and they may not be so highly correct in all points as Blacks and Duns, but they at once arrested attention to their slender and graceful properties.

Of Pouters we counted twenty-one birds all of great merit, the property of Mr. Gill. Especially we noted a superb Yellow cock. In contrast to it stood a black hen of highest worth to a fancier, together with Blues, winners of many prizes, and Reds of the highest merit. Mr. Gill would alone have contributed an excellent show. Mr. Holloway sent four good Whites, including a cock of remarkably narrow girth, of fine shape and proportions throughout. Next are Mr. Combe's Pouters, fourteen in number, also good, yet amongst them a conspicuously fine Red cock. Capt. Norman Hill's birds show the quality that holds its own in competition and wins high positions at the greatest of all Pouter exhibitions—Edinburgh. We were at a loss which to admire most, the champion Blue or Black cock. It is a treat to look upon either.

The Homing birds or Antwerps mustered well. Mr. Gamon sent eight Long-faced show Antwerps of various colours, in form symmetrical and powerful, and eight Short-faced birds perfect in head and beak. Mr. Tegetmeier showed a pen of fourteen Blue Chequers that looked every inch flyers. Mr. Theobald who exhibited for the first time sent two pens of Antwerps, beautiful in colour, in markings, and in shape.

Mr. Pratt exhibited fifteen Carriers, some excellent birds. A most interesting pen was contributed by Mr. Hives, Red Mottled Scanderoon, characteristic in shape of head and beak, and of a deep rich red. He also sent Jacobins—White, Blue, and Self-coloured Blacks. Near them were Mr. Pratt's Barbs and a second contingent from the loft of Mr. Combe, Black and Yellow Jacobins, Yellow Baldheads, Black Turbits, and Blue Owls.

We next proceed to a circle formed by the handsome and uniform mahogany pens of the Society, arranged around the fountain in the tropical department of the Palace. First was a pen tenanted by a very excellent and rare collection of Tumblers shown by Mr. Taylor of Rochdale, including Beards, some of the best ever seen, Black Mottles, well marked, dolphin-eyed, with good carriage, head and beak. Mr. H. Johnson's eight Almond hens were all of a good rich ground colour. Mr. Jayne's contribution—eighty birds—was a sight to be remembered. Agates, Kites, Yellows, Almonds, in all degrees of brilliancy and richness of colour here greeted the eye. Mr. Merok (President) exhibited Almonds (ten) all of good colour. More especially did we notice four Almond hens, the *élite* amongst the Almonds of our day. Mr. Heritage's pen contained Agates, Almonds, and Splashes of high merit.

This show afforded the unwonted sight of a second pen of Black Mottles, the property of Mr. Henning, a comparatively young fancier who has stepped into the foremost rank. His Black Mottles were charming birds. We much doubt if any better have been viewed since those so wonderfully good of Mr. Bellamy nearly bewildered the older fanciers. We hope such a pen of birds will be an annual treat to fanciers. The same gentleman's Almonds (twelve) were exceptionally good.

Next was a pen of very good Black Beards, some of them really excellent in all points. Such specimens of this now very rare variety were shown by Mr. South (Vice-President), who also owns a pen of clean-cut, good-conditioned Baldheads. Baldheads—Blue, Black, Red, and Yellow—were a pretty group contributed by Mr. Sprunt, who showed also Yellow, Silver, and Blue Owls of excellent colour. We now arrived at the pen of Powdered Silvers shown by Mr. Esquilant. Beautiful birds, such as we should expect from the loft of so renowned a fancier. English Owls were also shown by Mr. Jones and Mr. Schweitzer, amongst them some first-rate birds. A pen of Blondinettes—a most pretty variety—was exhibited by Mr. Schweitzer. His twelve African Owls—White, Black, and Mauve-tailed—were gems. Mr. Stevenson also had a nice pen of this charming though delicate variety. Next were ten of Mr. Hedley's noted Barbs of the most highly-bred type, then the like number of Mr. Heritage's stock, and twelve of Mr. Jones's. Worthy neighbours.

We were next among the Turbits viewing a fine pen of twelve Yellows, the property of Mr. Stevenson, very good in colour; and in contrast to them Mr. Taylor showed alongside eight Black Turbits of a quality seldom seen. Next were the Blue and Silver Turbits of Mr. Stevenson. To represent the Red Turbits Mr. South filled a pen with twelve birds of very grand colour, good in markings, and of fine shape. Blue and Silver Homings, excellent birds, were shown. That popular and showy bird the Fantail was well represented, Messrs. Maynard and V. D. M. having two pens of birds with good tails and carriage. A gathering of many kinds of Toy Pigeons as usual came from the loft of Mr.

Vander Meersch—viz., Trumpeters, Pigmy Pouters, Swallows, Spots, Magpies, together with a pen of twelve White Jacobins—an unusual sight.

We at length arrived at the Dragoons. Not so numerous as in some former years, yet a collection noticeable from the names of rising fanciers coming into notice by a display of promising birds. Mr. Sargent showed only for a second time. He has not been idle during the past year, and had some good Reds and Yellows. Mr. Thomas also could boast of his pen, for in it were specimens of exceedingly good birds. The older Dragoon fanciers were not absent. Of Silvers and Blues there were eighteen of Mr. Whitehead's (Secretary) birds that hold their ground well in competition. Mr. Batty also showed Yellows and Reds; Mr. Thomas, Blues. A pair of pretty Cumulets were penned by Capt. Hill. Pigmy Pouters by Mr. Hives. Magpies very good by Mr. Herbert.

It remains but to comment on the show of Jacobins, at present so fashionable a variety and in which the Society showed great strength. Mr. Hardy's contribution of Yellows, Reds, Turbits, and Mottles was excellent; good in style, closeness of frill and mane. Of Mr. Boyd's twenty-four magnificent specimens we cannot write as they deserve. They should have been gazed upon by the Jacobin fancier if he travelled far to do so. In his pens were grouped the most noted birds in England, and a stud we venture to say not approached in quality by any of the more modern fanciers, for Mr. Boyd's love of Jacobins date from years ago. The prize Yellow cocks were there; that gem of neatness the noted little Red hen, type of perfection; Red cock with exuberance of frill feathers, among which are interspersed long silken threads of the softest texture. Half-a-dozen Red Jacobins were sent by Mr. Easton; very pretty, neat, close-hooded birds. Mr. Easton's Jacobins are well known by visitors to the grand shows, and on this occasion they well sustained his high repute. Of Jacobins, a stud of ten Yellows in Mr. Bull's pen, we observed many an old Pigeon-lover examining with approving glances. They were large-frilled, round-headed, down-beaked. They well merited all the attention they attracted. Our description of this formidable array of Pigeons closes with the notice of a pen of fourteen Red Jacobins, the property of Mr. Batty, who now appears to have divided his care between his old strain of Yellow Dragoons and this variety. We wish him as much success in the latter as he has achieved in the former.

AMERICAN HONEY BOXES.

"WHAT! are you, too, going across the Atlantic to find evidence in support of your system of bee-keeping?" No, if bee-keeping in Great Britain cannot stand on its own legs, I shall never attempt to hold it up by American props. If we have much to learn I am sure we shall not learn it from our cousins on the other side of the water. There they have their own warmer climate, and will manage bees as best they can. From reading American books I have come to the conclusion that the practical bee-keepers of this country will never fill their honey pots by copying the American practice.

We have heard a great deal about the small boxes or supers of honeycomb which are so easily sold in American cities. These boxes are said to hold from 2 lbs. to 4 lbs. of honeycomb. A gentleman in this locality brought one of these American boxes for me to look at lately. It had come from America with honey in it, but was empty when it came here. It is very simply and cheaply made. The top, ends, and bottom are of wood, not quite half an inch thick, and the sides are of thin glass. It measures 6 inches long, 5 inches deep, and 2 inches wide—just wide enough for one comb. On the top of the box was a large black paper label with the following inscription in golden letters:—

CHOICE
WHITE CLOVER HONEY,
from the Apiaries of
J. H. MARSH, Sharon, Vt.

Honey put up in any style desired.
Wholesale and retail.

Well, here is evidence of Americans going ahead. Here is a box filled by American bees, sold in Boston, shipped to England, and emptied at Manchester. I was pleased to see the box, and as it was smeared with honey which had run from the combs, I scraped the glass and wood with a view to taste American honey. I gathered about two tea-spoonfuls of it, which did not appear or taste like English clover honey. If it was not sugar syrup I never saw or tasted anything so like it. I could not obtain a smack of honey from it. And the combs that adhered to the wood and glass were very much whiter than the combs made in this country from clover honey.

I shall try the small-box system this year, not with a view to profit, but to find out how many can be obtained from one stock hive in a season. If the season be a favourable one for honey-gathering, the experiment will, I think, be both interesting and instructive; and the readers of this Journal will have a full account of it at the end of the season. Whatever number be filled they will contain nothing but pure honey gathered by the bees from field flowers.—A. PATTERSON.

THE WONDERS OF A BEE HIVE.—No. 4.

ACCORDING to Walker's Dictionary "a drone is an idler or sluggard; a bee which makes no honey." Drone bees are twenty-four days in their cells, and are born amid an active community without receiving any attention. Their introduction to the world is without pageant, and during their lives they merit and receive but little patronage. They are clumsy unmannerly creatures, and quite incapable of culture or improvement. Their great characteristic is laziness—dronishness in early life and dronishness to the end. They have no inclination for a life of activity and usefulness, and seem to take no interest in the welfare of the community of which they form a part.

Knowing as I do the gloomy future they have before them, their early doom and suffering, sorrowful end, I can never view drone life without being touched with a degree of sympathy and sorrow. They are very unfortunate creatures, being without any weapons or means of self-defence, and seem somewhat conscious of their inferiority and worthlessness. In watching them going in and out of their hives, even in the heyday of their lives, we naturally compare them to galley-slaves, spiritless and hopeless. The climax of drone-life is wonderful and without parallel in the insect or animal world. Drone bees are bred and born by thousands in a natural way, but when and where do we find one dying a natural death?

Drones being males are produced in hives when their bees have to make all necessary preparations for swarming. The swarms take the old queens with them, but before they emigrate the bees prepare royal cells and place eggs in them, which speedily become perfect princesses ready to take the places and thrones of their mothers. The advent of swarming is generally preceded by the production of drones. Connected with the question of the production of drones and their matrimonial alliances we find many wonders and mysteries, but owing to their nature we shall do well not to mention them in this series of letters.

After, some ten days after, the bees discover that their young queens are laying in a satisfactory manner, they commence to worry the drones, which are harassed and persecuted more bitterly every day. Then the bees resort to the cruel process of hungering the drones by driving them from the combs down to the boards, where they can find no food. Here they may be found for days pining and languishing from sheer want. Literally they are being starved to death. Many of them may be seen on the flight boards with savage tormentors on their backs trying to escape, but where can they go to find a home? They are incapable of work, and are the most stupid, shiftless, helpless creatures possible. Friendless and homeless they can find no rest or sympathy anywhere. Truly the termination of drone-life is a chapter of horrors—rather painful to write, and painful to read.

There may be another production of drones later in the season. Hives may become full of brood in July and August, and when this happens another hatch of drones will appear. First and second swarms too may become full in July or August, and prepare for swarming by setting a great number of drone eggs in drone cells. Thus a second massacre of drones becomes necessary, and generally takes place in September. In hives that have lost their queens, or possess worthless queens, the bees do not kill their drones.

In most hives far too many drones are reared. In all such too much drone comb has been built. It is a stroke of good policy and management to have hives with very little drone comb in them. When we come to write on practical matters we may have something to say on this subject. Within the last five years drone traps have been invented and introduced. They are clever inventions, and answer pretty well. They are placed on the mouths of hives, so that all the working bees in going to the fields pass through the traps. The drones go into the traps in leaving the hives, but being larger than workers they cannot pass through. They are caught thus and easily destroyed.

Perhaps the best way of ridding a hive of its drones is to drive all the bees and drones into an empty hive, catch the queen, and put her with a few bees back amongst the combs of the hive, and place it on the old stand; then put the queenless swarm on board, raise the hive high enough to let the workers come out. In less than an hour the bees will have left their drones in a state of confinement to the mercy of the bee-master, and it will be an act of mercy to destroy them speedily.—A. PATTERSON.

OUR LETTER BOX.

DORKING AND GAME CROSS (Scotch Grey).—You will have difficulty in finding a harder fowl than the Dorking crossed with Game. They will be good egg-producers if you keep early-hatched pullets that will attain to maturity in the winter. Pure Game are harder than the cross between them and Dorkings. The disadvantage is their pugnacity. We should prefer the Houdans. You will find good mention of the Game in all the poultry books. We know no book especially devoted to that breed. It is well to remark the Houdans do not sit, nor do the Spanish.

GRAY AND SILVER-GRAY DORKINGS (J. C.).—There is no defined colour for the Grey Dorking. The Silver-Gray cock must have an entirely black breast and tail, very light hackle and saddle—not one white spot on the breast, and no colour on the wing but metallic black with silver bar. The hen should have a black-and-white striped hackle, a robin breast, light grey feathers all over the body, each having a white shaft; no white spots on the plumage. They are difficult to breed correctly, as, being birds of feather, a trifling fault becomes a fatal one.

CRACKS IN CEMENT (E. S. W.).—There is no mode of filling the cracks than by inserting some of the same kind of cement.

REMARKS.

26th.—Foggy morning, but clearing off by noon, and fine the remainder of the day.

27th.—Very thick fog all day; a few gleams of sun about 1 P.M., but the fog very dense about 8 P.M.; clearer towards night.

28th.—Very foggy, but the sun managed to get through it occasionally in the middle of the day.

29th.—Dense fog in morning, but the sun shone brightly in the middle of the day in spite of the still remaining fog, which got more dense and damp towards night.

30th.—Fog in morning, rain at noon, and very damp all the rest of the day.

31st.—A clear, bright, pleasant day throughout.

Feb. 1st.—Rather thick all day, but not near so much so as during the past week; rain at night.

High barometer, scarcely any wind, much fog, and little rain.—G. J. STYMONS.

COVENT GARDEN MARKET.—FEBRUARY 2.

THERE is very little alteration to report from last week. Late Grapes are still in good supply and fair demand. A fine sample of Ash-leaved Kidney Potatoes from Jersey has been in the market. All kinds of green stuff are now coming in fair quantities, and can be bought at reasonable prices.

From observations taken near London during forty-three years, the average day temperature of the week is 46.9°; and its night temperature 30.0°.

ROSE CULTURE AND EXHIBITING.

"Queen of the flowers which made Eden gay."

WHEN I began Rose-growing I thought the grand desideratum was the greatest possible number of varieties of Roses. I can remember well how I bought every Rose to be found in such catalogues as William Paul's, and how I thought that Mr. Keynes' selection was far too small to give one a chance of success at the shows. I soon, indeed the very first season, found out my mistake, I had spent scores of pounds on summer Roses including all the cripples that some are so fond of. I remember going through my grand list with Mr. Keynes, and how he laughed as name after name of varieties utterly worthless were read out. What was the consequence? Why, my garden, all virgin soil that I had hauled there at tremendous expense, was full of Baron Prévost, Empereur de Maroc, Achille Goned, Madame Chirard, Austrian Briars, Juno, Chénédoie, Blanchfleur, &c., and when I came to cut for the shows, of all the good sorts I had only about two or three specimens. I had, consequently, to throw or give away hundreds the next autumn.

By long experience I found out which are the very best, and now I confine myself to about fifty, or at the most sixty, sorts, of which I grow a fair number—I mean by a fair number from ten to twenty. This number would give an amateur a collection of about a thousand, which is as many as most men can do with. Now, when the time for staging arrives there is no difficulty in cutting a stand of good sorts.

As to what those sorts are no one need be a moment in doubt, for they have but to send to your office for the number of "our Journal" which contains the Rose election return and they will there find a list of as many Roses as they want to buy placed in order of merit. I am, of course, writing these notes principally as an exhibitor and for exhibitors, though I hope the advice may be serviceable to all Rose-growers.

Next, as to the place in your garden (the position) where you ought to grow your best specimens. I feel confident that the more open the position is the better the Roses will do. Of course the Roses must face the south or south-east, but what I mean is, the idea of protecting Roses by walls or other screens is a false one; at least, I have proved it here to be so.

I have just made a grand new bed to contain about a thousand Roses. I have been lifting Roses from all other parts of this absurdly large place to plant them in the new bed. Well, every Rose that has been grown against a wall is almost worthless. One side of the wood is green and the other side is hard, barkbound, unripened wood, fit for nothing but our very mediæval fireplaces.

The wood of the Teas does not ripen here, at least when they are planted against walls.

I expect this statement to be violently contradicted, and I only hope it will cause discussion, because every

article that has to do with Roses is so welcome to the readers of our Journal. My friend Mr. Baker can endorse what I have said as to my own Teas, and I believe Mr. Headley, Mr. Jowett, and other large Tea Rose-growers will support me too.

Of course climate makes all the difference; I am speaking of the west of England, where we have not ever very hard or long frosts. I know that my brother in Yorkshire cannot bloom a Tea unless it is either against a wall, or in his Tea-Rose house. I mean a genial climate to be taken for granted in all I write on Roses; for I should write in a perfectly different style if I dated this letter from Yorkshire instead of from the lovely Monkton Wyld.

My idea of a gem of a position for a rosery is such as I am now forming. A portion of an old meadow has (by my friend Mr. Baker's advice) been railed-off just below the kitchen garden. There is a very low wall at the back, above which are espalier Apple trees, and about 20 yards further away to the north is the Peach wall which shuts in the garden. To the east of the rosery there is a plantation of Fir trees, and to the west another of high Hollies, Laurels, &c. To the south there is not a tree or a single obstacle to stop the free current of air. Planted in simple straight rows are about forty-eight sorts, and from ten to twenty of a sort according to the excellency of the variety. So that when staging for a show the boxes can be placed under the Fir trees, and the Roses cut and staged in a very short time. This is Mr. Baker's plan, and he is the most successful amateur grower in the world.

It is important to have your Roses together when the exhibition season has arrived. I can remember so well how I used to have to run with two blooms in each hand and one between my teeth at least 800 yards before I could stage them. For we cannot well adopt the nurseryman's practice of sending two boys with a box which the foreman fills and then sends back to the staging shed; we should require no end of men or "lady helps" to do this.

Any advice as to staging must be of use, as when the day arrives how fast time flies, and what hard work it is to have your blooms out and staged before the sun becomes hot! As to staging, then, I would say this—Have your boxes ready the night before and placed in a row. Say you are showing in all the classes at a great show, place your forty-eight first, then thirty-six next, then twenty-four, and so on. Then commence to cut the variety you mean to begin your boxes with. I always start mine with that grandest of Roses Charles Lefebvre; Mr. Baker is very fond of Madame Charles Wood. Cut as many good suitable blooms as you can find and take them to your boxes, and place one at the beginning of each stand, then go back and bring the next, and so on. The blooms then never leave your or your man's hands till they are placed in the tubes. If you cannot rely on your knowledge of the different sorts you must have some one to find the labels and place them in front of the Roses as you bring them in. When all is done close every box, and have them taken down into your wine-cellar. Then open the lids wide, lock the cellar, and leave them in solitude

undisturbed by anyone (however dear *she* may be) till you place them in your carriage for conveyance to the train. But before you remove the boxes from the cellar you will have to run round your nursery and out every likely young Rose for your spare box. It is of the greatest importance that these should be very young, for you never know what sort of a night you may have, and a journey always opens blooms quicker than anything else. There are also many blooms which open more quickly than others, and have to be cut very young indeed.

I think I have shown my hand sufficiently for one letter. If, however, my dear old friends the head Rose nurserymen would only add to their descriptions of the Roses in the catalogues such words as "A good traveller;" "must be cut very young;" "loses colour on the road," &c., they would confer a boon on hundreds of exhibitors. But this is one of the things that nothing but experience—experience gained, too, by repeated sad failures—will teach, and we must all gain it in the same way. There is no Rose here on earth without a thorn, and the Rose exhibitor cannot attain to that envied position of first-prize holder at the Crystal Palace without hard work, frequent disappointments, many heartburnings, and incessant loving care. But who will grudge all this in the cause of the Rose? What worshipper at the shrine of Flora's choicest gift will hesitate to offer that which costs him most of all—his incessant labour, his constant love? and if even once she answers his prayer and rewards his constancy by placing him first at her fête in the Palace of crystal he will be more than amply repaid for all his toil and care and love; and as he pledges her in the wine that bears her name and drains a bumper of Chateau La Rose in honour of his victory, there will be but one thought dominant in his heart, and that will be the hope that each year will make the Rose more honoured and loved. *Vivat Rosa regina florum.*—JOHN B. M. CAMM, *Monkton Wyld.*

LILY CULTURE AND LIST OF SPECIES AND VARIETIES.

SINCE the advent of *Lilium auratum* in 1860 there has been quite a rage for Lilies, and many new species and distinct varieties have been introduced subsequently from Japan, California, the Philippine Islands, &c. All of them may be cultivated in pots, and nearly the whole of them in the open ground in England. When the bulbs are planted out of doors they should be in a position where the plants will not be exposed to the fury of south-west gales. Not only the flowers but the leaves also are much injured by wind.

The culture in pots is very simple, and may be briefly described. When the flower-stalks become yellow it is a sign that they may be cut down near the surface of the ground, and as soon as convenient after this the roots may be repotted. There is some difference of opinion amongst Lily growers as to the best way this is to be done. Some hold that it is injurious to the bulbs to shake them out of the soil and separate them, and would repot year after year, increasing annually the size of the pots. If the roots are potted before they start into growth I believe it is the best practice to shake out all the old soil, and saving as many as possible of the fibrous roots at the base of the bulb. There will also be a larger proportion of fibrous roots at the base of the old stalks, and these will have grown all round the bulb. The best way is to twist this stalk with all the roots out from the bulb.

I have tried to grow them in various composts and they do well in loam, leaf mould, and decayed manure. They do equally well in a compost of turfy loam and turfy peat in equal proportions, the leaf mould to be omitted, but adding the same proportion of manure and sand; one-fifth part of the compost ought to be well-decayed manure. I have always found that the roots are in better health when peat has been used in the compost. Good peat cannot be obtained in all districts, but when it can I advise its use; but it is as well to state that very fine Lilies can be grown without peat in the soil.

I believe in carefully draining all pots intended to grow plants during a whole season. The crocks should be placed in carefully, one large piece over the hole, a few similar bits of crock should be placed over it, and some smaller drainage over all; the finer portion of the compost must be prevented from mixing with this by placing fibrous turf over the crocks. In potting press the mould in firmly by the hand, but not hard. The pots used may be of various sizes, one bulb in the centre of a 5 or 6-inch pot, or a dozen or a score of roots may be

potted in a 18 or 15-inch. I have also potted three or four roots in a 9-inch pot; the top of the bulb should be an inch or more below the surface. After potting plunge the pots out of doors in some light material—I find cocoa-nut fibre refuse very useful for this purpose; the surface of the pots should be at least 6 inches covered. Early in February they must be taken out of the plunging material and be put into a cold frame. By this time plenty of new roots will have formed, and some of the early sorts be throwing up the flower-stems. Abundant ventilation is necessary, and in fine weather the lights may be removed. When all danger of frost is over the plants may be removed to a sheltered position out of doors, or they may be kept through the season under glass; if the latter, the plants should be close to the glass, the house to be well ventilated, and the ventilators open night as well as day. I have had *L. auratum* and *L. Humboldtii* run up to 8 or 10 feet under such circumstances, and be well furnished with leaves from the base. The flower-stems require to be supported by sticks, and when in flower they must be shaded from the sun.

As to sorts, *L. auratum* must stand at the top of the list. Amongst the importations from Japan are many inferior varieties, but the best selections are truly noble flowers. *L. Krameri* and *L. Krameri album* are very much like *auratum* in style of growth and formation of flower; the petals of the former are suffused with pink. *L. Leichtlinii* is a very beautiful flower of slender growth; the petals gracefully recurve. They are clear yellow, spotted with brownish purple. There is also a major form which is scarce.

L. speciosum, of which there are at least six distinct and very beautiful varieties, is, perhaps, the most useful of all for pot culture. *L. Humboldtii* is a very showy species, the flowers are orange yellow densely spotted with brown; the petals are recurved, and the whole flower resembles *L. tigrinum splendens*. *L. californicum* and *L. pardalinum* are nearly allied species. *L. longiflorum* with its elegant trumpet-shaped, clear white flowers, should be in the most select collection. *L. Washingtonianum* is a handsome species, but it is not such a fine flower in cultivation as it was expected to be from the glowing accounts received with it. *L. umbellatum* and its varieties *L. Thunbergianum* and numerous forms thereof are all worthy of culture. *L. giganteum* is a grand species and likes a shady sheltered position in which to develop its magnificent spike of flowers. *L. tigrinum splendens* is the best of the Tiger Lilies. *L. tigrinum fl.-pl.* is also a very fine variety. *L. tenuifolium* is a gem, the stem is a foot high furnished with narrow leaves, and the flowers are orange scarlet, the petals elegantly recurved. *L. parvum* is also a small dwarf species worthy of culture.—J. DOUGLAS.

THE ARRANGEMENTS OF COLOURS

IN THE BEDS OF THE LONDON PARKS AND GARDENS.—No. 5.

COLOUR gives to the world beauty and ornament; it aids us in determining distance and space, and enables the eye more readily to separate objects. All colours are contained, in light, in a state of combination, and are found to resolve themselves into three primary colours—viz., red, yellow, and blue, and three compound or intermediate colours, each formed by the union of two primitive colours. These compound colours are purple, green, or orange. Mixtures of these secondary colours produce the tertiary colours, which are softer and less definite. Black and white may for all practical purposes, whether in painting, floriculture, or landscape gardening, be considered as colours. Painters describe colours as being warm colours or cold colours, orange and red and those hues and tints being warm, blue and green being cold colours. Yellow is of all colours the most allied to light, while its complementary purple is the darkest of hues; they contrast, therefore, as to light and dark—that is, in reference to light alone. Red is the most exciting and positive of all colours, its complementary green the most soothing and grateful to the eye. Red and green are non-contrasting as to light and dark, but they are contrasting as to their powers of exciting the eye and as to the power of colouring.

Blue is the coldest and most retiring of all colours, its complementary orange the warmest and most advancing. The contrast is, therefore, both as to advancing and retiring, and as to hot and cold. Thus it will be seen that the orange is complementary to blue, and blue to orange; purple is a complementary to yellow, and yellow to purple; green is a com-

plementary to red, and red to green. To discover the complementary of any given colour, say red for example, you have only to fix the eyes earnestly on a spot of black and then on a spot of red, when a dim circle of green, the complementary colour to red, will be seen around the red spot. In the like manner the complementary colour of purple will be found to be orange, and of blue yellow.

Fig. 26.—Bed E.

The simplest arrangements of colours are the combinations of the primaries and secondaries, yet that these combinations be perfectly harmonious requires great skill in their distribution, otherwise their characteristics of simplicity speedily degenerate into coarse vulgarity. Nothing is less brilliant than flower beds in which the only colours to be seen are blue and white. Nothing is more gaudy than a garden stocked with a profusion of yellow and little else. It is very unsatisfactory also to find flowers but of different shades placed near each other, and all these errors of taste should be avoided.

In order that a garden may be showy and attractive the grand principle in the employment of colours is never to employ a compound colour between the two primitive colours which compose it. For example, purple ought never to be employed between blue and red, green between blue and yellow, or orange between yellow and red. Blue flowers should be placed near orange, violet next to yellow. Reds and pinks look well when surrounded with a border of white or grey. Each primitive colour should be contrasted with its complementary one, which will always be found to be a compound one. Thus red is a primitive colour, but green is a compound one; yellow is a primitive colour, but purple a compound; and blue primitive, orange compound.

In the case of employing primitive colours in a combination without the compound or intermediate colour one should be planted in large, and the other in small quantities. One primitive colour may be opposite to another, and will have a good effect. For example, adjoining a mass of blue there may be specks of red or yellow, but the primitive colours have a better effect still when the specks of blue, red, and yellow are

dotted in a mass of compound colours, and thus nothing is finer in effect than a mass of green with two or three specks of red or bright yellow. The same principle will hold good with white or black, and thus a speck or two of bright, light, or clear-shining black may be placed adjoining or among objects of any colour whatever. When I speak of black it applies to foliage, not flowers; indeed, there are no black flowers that I

Fig. 27.—Bed F.

am aware of. The following examples of planting circular beds effectively are submitted.

BED E.

1. Lobelia Blue King.
2. Alternanthera amena spectabilis.
3. Alternanthera paronychioides major.

4. White Lobelia.

5. Stellaria graminea aurea.

This bed would look best on a sloping bank.

BED F.

1. Coleus Verachaffeltii.

2. Leucophyton Brownii.

3. Lobelia Blue Stone.

4. Alternanthera magnifica.

A deep claret colour.

5. Stellaria graminea aurea.

6. Echeveria secunda glauca.

7. Sempervivum montanum.

BED G.

1. Iresine Lindenii and Gazania splendens, planted alternately.

2. White Lobelia.

3. Blue Lobelia.

4. Golden Pyrethrum.

5. Echeveria secunda glauca.

KEEPING GRAPES LATE.

I quite agree with your correspondent "W. E." that good late Grapes can be had even with the disadvantages of growing plants in the vineries. I had charge of a late vinery in my former situation, Chilworth Manor Gardens, in which were greenhouse plants, &c., and we, like "W. E.," took advantage of a dry clear day to water the plants, then mopped the water up dry, having opened both front and top ventilators to thoroughly dry the house. We were never troubled with mildew, the Grapes keeping good till the middle of February, when those remaining were cut from the Vines, the stems of the

bunches being inserted in bottles with a little water and a piece of charcoal in each bottle to keep the water sweet, and suspended in a dry room till the Grapes were required for table.

The varieties were Lady Downe's, West's St. Peter's, Muscat of Alexandria, White Nice, and Black Alicante; the last two being the best, carrying the heaviest bunches, Black Alicante weighing on an average nearly 3 lbs. when cut from the Vines.

I see reference has been made to Gros Colman Grape. My experience of it will not speak much in its favour. We had it in a cool vinery where there was but little or no fire heat, by the side of Black Alicante, Muscat of Alexandria, and Mrs. Pince, all of which set and ripened without the aid of any fire heat whatever. The bunches were everything that could be desired, but not so with Gros Colman; this Grape was badly coloured and very deficient in flavour. It was discarded altogether from our collection. Mr. Batters, gardener, Chilworth Manor, informed me some weeks ago that he paid a visit to Heckfield last season and saw it there in splendid condition, Mr. Wildsmith thinking very highly of it.—F. H. FAUD.

AURICULAS.

IF "ALFRED" be an enthusiastic man, the letter in page 87 will have chilled him. In order, therefore, to give him a few grains of solace, and to show that he can live very comfortably without having either Page's Champion or Taylor's Glory, let me extract from Glenny's "Annals of Horticulture" for 1847 what is said in disparagement of these two varieties, though in other respects they are duly praised. Page's Champion "is of uncertain texture, apt to crack in the paste, and occasionally very much crumpled. The paste rather thin. The divisions of the petals often go quite through the colour. The pips generally want fatness. By growing a number of them we may pick one fit to exhibit." Of Taylor's Glory another writer, in page 415, says, "Paste not circular, ground colour breaks through the edge. In my opinion it is much overrated."

When these opinions were given the plants were to be had. I bought a Champion at Dickson's in Acre Lane for a few shillings, I think 5s. Now they are nearly lost and cannot be bought the desire of possessing them has increased, and fancy throws over them a halo which conceals defects that were visible enough when they were cheap and common.—G. S.

ROYAL HORTICULTURAL SOCIETY.

The Annual General Meeting of this Society was held on Tuesday at the Council-rooms, South Kensington; but owing to the fact that Parliament was opened on the same day the Council very properly had it announced in all the papers that the annual meeting for the dispatch of business would not be held until Thursday the 10th inst. However, at a thinly attended meeting yesterday the Hon. and Rev. J. T. Boscawen took the chair in the absence of the President, Lord Aberdare. At the Council board there were present Mr. Webb, the Treasurer; Dr. Hogg, the Secretary; Mr. Little, Dr. Denny, Mr. Warner, Mr. Kellock, Mr. Haughton, &c.

The CHAIRMAN.—Ladies and Gentlemen, I suppose you will take the report as read.

SEVERAL MEMBERS.—Certainly.

The CHAIRMAN.—Well, then, ladies and gentlemen, I would ask you, under the circumstances, to have this meeting adjourned until Thursday next, because it would be very unfair to arrive at any conclusion with respect to the affairs of the Society without having a full meeting of its Fellows. It would be utterly impossible for us to come to a conclusion upon the very serious question before us on this occasion [hear, hear]. I think the proper thing to do is to adjourn the meeting [hear, hear].

Sir PETER POLZ said he, for one, in the interest of the Society, wished to see the meeting adjourned to a day when all the Fellows of the Society could, without hesitation, express their opinions.

The question of adjournment was then put to the meeting, and on a vote being taken it was resolved to proceed to business. The ballot was then taken, and the following was the result:—President, Rt. Hon. Lord Aberdare; Treasurer, Henry Webb; Secretary, Dr. Hogg; Expenses Committee, F. Campion, Henry Webb, and Vice-Admiral W. W. Hornby; Auditors, Conrad H. Pinches, James F. West, and John Lee. Mr. H. J. Veitch then moved that this meeting be adjourned till Thursday the 10th inst., and this was carried unanimously.

REPORT OF THE COUNCIL TO THE ANNUAL GENERAL MEETING.

THE most important work which the Society has been able to accomplish for the advancement of the science and practice of

horticulture during the past year will be found in the Report of the Chiswick Board of Directors. The Council congratulate the Fellows on the useful work which has been done in the garden at Chiswick in the way of determining many new varieties of fruits and vegetables, and in testing the merits of a large variety of the new flowers which are employed for the adornment of gardens. They especially call their attention to the important discovery that has been made by Mr. Worthington G. Smith, a member of the Scientific Committee, who has detected the resting spores of *Peronospora infestans*, or Potato blight, the particulars of which were first given to the world at the meetings of this Society. By this valuable discovery light has been thrown upon the life and economy of this national scourge which, it is hoped, will enable physiologists to suggest a means to check and ultimately destroy this disease which has for so many years interfered with the production of this important article of food.

The three Committees entrusted with the scientific and practical operations of the Society have regularly met during the year, and the reports of their proceedings have been published in the current horticultural periodicals. The low state of the Society's finances led some time ago to the discontinuance of the Journal, and, as a medium of communication between the Fellows as to the result of the Society's operations, recourse has been had to existing publications. The Council regret that they have not been able to recommence the publication of the Journal; and, should there be such an improvement in the revenue as to warrant them in doing so, they will lose no time in re-issuing it.

In the early part of the year it was found impossible to adhere to the schedule of prizes offered at the flower shows at South Kensington, and the Council then in office announced the necessity of reducing the prizes by 50 per cent. This proceeding dissatisfied many of the exhibitors, who thereupon refused to send plants, and the exhibitions suffered greatly in extent and beauty. This falling-off was apparent at all the early shows, which in consequence did not attract as many visitors or yield as much money at the gates as was expected.

On the reconstruction of the Council in June last the exhibitors who had held aloof from previous shows determined to make a gratuitous display in order to prove they were not influenced alone by the offer of prizes, and there was held on the 21st July, under the large tent, one of the most magnificent shows of the kind ever seen in the gardens at South Kensington. To those gentlemen who came forward so liberally to support the Society at a time when it was surrounded with many difficulties the best thanks of the Fellows are due.

The Council would remind the Fellows that to keep up the horticultural attractions of the gardens, as well as to promote and encourage the science and practice of horticulture, it is necessary to maintain these horticultural exhibitions; and to do this, as well as to provide for the general working expenses of the Society and the interest on the debt, it is necessary that the revenue be increased much beyond what it has ever yet reached. The income of the Society has never, without extraneous assistance, been sufficient to meet the expenditure. For two years, when the International Industrial Exhibitions were held in the adjoining buildings, and certain concessions were made to the Society by Her Majesty's Commissioners, the revenue was sufficient for all requirements, but in no other year has it ever been so. It was, therefore, with the object of raising the revenue that the Council most unwillingly felt it their duty to revise the existing privileges of Fellows, and to reconstruct them on such terms as they considered would attain the desired result.

It will be seen on reference to the balance-sheet that the debts bequeathed by former Councils still remain at upwards of £4,000, and although the revenue of the year has been lessened by £800, it has been at the cost of the prize list.

The agreement with Her Majesty's Commissioners has not been completed, but the terms, as previously announced, have been arranged, and the Council rely upon the co-operation of the Fellows for an increase of income to enable them to carry out the objects of the Society, and to maintain in efficiency and attractiveness the gardens both of Chiswick and South Kensington.

REPORT OF THE CHISWICK BOARD OF DIRECTION.

The Board of Direction at Chiswick report that a great deal of good and important work has been carried on during the past season.

That the crops of fruit have been plentiful, but owing to the great want of sunlight and extreme moisture, not only has the flavour been very inferior, but many varieties have decayed prematurely, an observation which seems to apply very generally throughout the country.

The matter of the greatest interest which came before the Board, as regards the fruit and vegetable department, after the adjudication with respect to the trials of Onions, Celeries, and the more perfect definition of the several varieties of Cabbages, of which the Society possesses a very complete collection, is the discovery, which has so long been a desideratum,

of the resting spores of the *Peronospora*, to which the formidable *Potato murrain* is due.

Some peculiar features soon manifested themselves in a large collection of American varieties of Potato, which are under experiment. It was not, indeed, the first time that these features had been observed, for they were well known to Mr. Barron, who had remarked that they were far more pronounced with respect to English-grown sorts than with those which were immediately imported from America. Indeed, these latter seemed free from disease. During the early part of this year the disease was so prominent, not only in the garden, but generally over the country, as to call more general attention to the subject. It was, indeed, intimated that the matter was exaggerated, or, indeed, was altogether denied; but the slightest inspection showed that there was enough for serious injury. Some peculiar bodies had been observed in the blackened leaves, which were supposed to belong to some species of *Protomyces*; but Mr. Worthington Smith at once conceived that they might be the long-sought resting spores, and carried out the matter so perseveringly that he arrived at complete certainty on the question. It remains only to be observed how these resting spores may comport themselves when germinating in the spring, and we trust that Mr. Smith will add to the honours which he has so well merited, that of ascertaining this closing point in the life history of this destructive pest.

POMOLOGICAL DEPARTMENT.

The crop of fruit of all kinds has been unusually abundant in the garden this year, and many varieties which have not hitherto fruited have been observed, and descriptions of them have been made. An opportunity has also been afforded for correcting erroneous nomenclature, and of ascertaining synonyms.

The varieties of Currants have for many years been very much misunderstood, great confusion having existed as to their nomenclature and identification. A collection of as many kinds as it was possible to obtain, both at home and abroad, was secured, and the number of reputed kinds planted in the garden amounted to fifty. When these were examined, and compared one with the other, it was found that there were only sixteen distinct, twelve of them being red, one flesh-coloured, and three white.

One of the largest experimental trials of Onions which has ever been undertaken was carried out very successfully. 158 samples were sown under 98 different names. These were all carefully compared and referred to their proper sections, whereby that large collection of reputed varieties was reduced to twenty. A full report of this trial has been already published, and as this was confined to the spring-sown sorts, the remainder, consisting of the Tripoli and Silver-skinned sections, are now under trial as autumn-sown Onions, and will form the substance of a future report.

A trial of all the varieties of Celery was also very successful, and out of forty-seven sorts that were sown, twenty proved to be distinct. A full report of this trial has also been published.

An attempt was made to obtain a full report on the numerous varieties of the Kidney Bean, but the season being cold and ungenial this proved a failure, and another trial will be made this year.

An attempt was also made to investigate those varieties of Potatoes that had not been included in the former trials, but the virulent attack of the Potato disease to which they were subjected rendered the experiment a failure.

A complete collection of all known varieties of Cauliflower has been sown for trial during the present season.

The distribution to the Fellows consisted of 965 packets of cuttings of fruit trees, comprising Apples, Pears, Plums, Cherries, Vines, and Figs, and of 17,062 packets of vegetable seeds.

The important discovery of the resting spores of the *Peronospora infestans* in the tuber of the Potato will no doubt be referred to by the Botanical Director. It was found that the disease this year attacked chiefly the new American varieties, grown from home-grown seed of the second year after their introduction, and it has been further remarked that all those new American Potatoes which produce such enormous crops from newly-imported seed rapidly degenerate year by year after their introduction, and that the produce gradually becomes smaller and of inferior quality.

The extensive collection of Strawberries which was planted for the purposes of trial promises to trial well this season.

FLORAL DEPARTMENT.

The work of the past year in the Floral Department has been in some degree crippled by the diminished facilities granted to the Superintendent. Nevertheless, under the circumstances, some very good work has been accomplished.

The trials of plants and flowers constitute some of the most important work done in this department—work which is of much public utility, since the experienced judgment of the Floral Committee, to whose labours for many years the Society owes so much, is brought in this way to bear upon subjects which are

all grown under identical conditions. The conclusions arrived at by the Committee form, consequently, a tolerably safe guide in the selection of subjects adapted for the climate of London, and for districts in which the climatal and geological conditions are in any degree similar. During the spring months the Committee examined the collection of bedding Violas which Mr. Barron had got together, consisting of some eighty-two varieties, and amongst them seventeen certificates of merit were distributed. Later on, a collection of Fuchsias, grown alike in comparatively small pots, and consisting of 126 varieties, underwent the scrutiny of the same body, and on this occasion twenty certificates were awarded. These were cultivated under glass. In the open-air beds a large contribution of Zonal Pelargoniums, from the principal nurserymen and florists, and consisting of 850 varieties, was planted out, and amongst them seventeen certificates were distributed. Besides these subjects, considerable collections of Phloxes and of Pentstemons were planted for inspection and comparison.

The plants prepared at Chiswick for the decoration of the garden at South Kensington always draw heavily on the labour and other resources of that establishment. During the past year there have been provided in this way, and devoted to this object, 12,000 flowering plants for the ornamentation of the conservatory, and 52,000 for bedding-out in the garden.

The conservatory plants, calculated at the low price of 1s. each, give a return of £597 16s.; and the bedding plants, valued at from 1d. to 4d. each, a return of £457 17s., making a total of £1055 18s., the whole expenditure on maintaining the garden during the past year being only about £1500.

The following are the subjects which have been distributed amongst the Fellows from this department—namely, plants of various kinds, 2000; cuttings of various kinds, 523; packets of seeds, various, 81,632.

The Directors have again to express their regret that the slender means at their disposal does not permit them to engage in those experiments in scientific floriculture and horticulture, and in those illustrations of modern practice, for the proper and efficient carrying forward of which, as being the national exemplar, the public has a strong claim upon the best efforts of the Society.

M. J. BERKELEY.
R. HOGG.
T. MOORE.

NOTES AND GLEANINGS.

FIFTY FELLOWS have been elected by the Royal Horticultural Society between April and December of last year.

— Owing to the disastrous effects of the *PHYLLLOXERA* in the French vineyards, the desirability of importing stocks from America was urged on the ground that the vigorous character of the American varieties were by that insect invulnerable. This appears, however, to be simply "tall talk," for a correspondent in the *Prairie Farmer* reports that he has recently taken up 2000 Vines in nearly twenty varieties, and that every sort was infested; the strong growers, however, being the most free from the pest, but all were attacked. The "little villains were found on the roots by millions."

— ACCORDING to Professor Bottger, a moderately concentrated solution of caustic soda or potash seems to promote the GERMINATION of SEEDS even more than ammonia. Seeds after soaking but a few hours in diluted potash solution put forth radicles.

— At the Tiverton Horticultural Show to be held on May 24th and 25th, the following SILVER CUPS are announced, in addition to a liberal schedule of prizes. For eighteen stove and greenhouse plants a silver cup value £20; for twelve Azaleas a cup value £15; for twelve Roses in pots a cup value £10; and for nine Pelargoniums a cup value £8.

— *LAPAGERIA ROSEA*, writes a gardener, is hardier than many people imagine, and states that at Gunnersbury Park a portion of the plant has protruded from the inside to the outside of the house, where it has grown and flowered for two years without any protection whatever. The frost of the recent winter destroyed the flowers, but has done no apparent injury to the shoots that had produced them.

— We have to thank the Hon. and Rev. J. T. Boscawen of Lamorran, Cornwall, for specimens of the CORNISH GILLIFLOWER APPLE, which exceed in size and excel in flavour any we have ever seen before. They are within a very little of being 4 inches long, and they are peculiarly snouted and ridged at the apex. The flesh is the deepest yellow we have ever seen in this variety, and may be described as yellow as an omelette.

— THE double-flowered Pelargoniums and Cinerarias are to be followed by DOUBLE-FLOWERED BEGONIAS, some varieties of the tuberous-rooted section being announced by M. Lemoine of Nancy. It is only the male flowers of each fascicle that are double, the female flowers retaining their normal form. Of these varieties B. Gloire de Nancy is in colour rich vermillion, and B. Lemoinei orange scarlet. They are to be distributed during the ensuing season.

— BRITISH Consuls in Brazil notice the extraordinary floral wealth of that vast empire. Their reports in 1875 call attention to the abundance of the trees from the juice of

which *INDIARUBBER* is prepared. At Aracaty this has recently become the most valuable article brought into the produce market of that place. From Bahia Consul Morgan sends a translation from a book published by the Inspector of the Custom-house of that port, in which it is stated that the consumption of a century would not exhaust the supply of india-rubber. The Inspector gives an account of a very remarkable tree, the *CARNAUBA PALM*, which grows in Brazil without any culture, and it is so hardy as to flourish in the most prolonged drought, and has often served at such times as the means of support to the population of more than one province. The top when young is an appreciable and nutritious article of food; and from this tree also wine, vinegar, and a saccharine matter are extracted, as well as a kind of gum, similar in its taste and properties to sago. From the wood musical instruments are made, as also tubes and pumps for water. The delicate fibrous substances of the pith of the stalk and its leaves make a good substitute for cork. The roots have the same virtues as the sarsaparilla. The pulp of the fruit is of an agreeable taste, and the nut oily and emulsive, is roasted and then used as coffee by many persons. From the trunk are obtained strong fibres, and also a species of flour similar to maizena, and a liquid resembling that of the Bahia Coconut. From the dried straw are made mats, hats, baskets, and brooms, and large quantities of the straw are exported to Europe for the manufacture of fine hats. Finally, from the leaves is produced the wax used in the manufacture of candles; and the export of this wax exceeds £162,000 a-year in value. The Inspector suggests that perhaps in no other country can there be found a plant applied to so many and varied purposes.

— FROM the report of the New Jersey CRANBERRY ASSOCIATION it appears that there are 15,000 acres of land in America devoted to Cranberry production, the average value of the crop being \$4,375,000. Last year the crop is estimated at 210,000 bushels. The crops in 1872 and 1873 were 275,000 bushels.

— THE Committee appointed to award the POTATO PRIZES offered by Messrs. B. K. Bliss & Sons in America have issued an elaborate report. The competitors, as might be expected, have "whipped" the "Britishers" who have been engaged in a similar enterprise in the "old country." The returns of the American prizewinners in raising the greatest weights from 1 lb. of seed credit Mr. Wood with producing 1417 lbs. of Snowflake, and Mr. Perkins with raising 1666½ lbs. of Kureka; the whole of the twelve prizetakers returned weights of over 1000 lbs. with both varieties. Further experiments have been made as to the most profitable distances at which to plant Potatoes, the results varying from 378 bushels per acre, the sets being 2 by 3 feet; to 441 bushels, the sets being 3 by 3½ feet apart.

— THE growth of MELONS in SPAIN is so much in advance of the immediate consumption, although poor and rich alike almost live upon them during two months of the year, that the gardener cuts thousands just before they arrive at maturity and hangs them up for the winter. Half or three-quarters of an acre produce no less in a favourable season than 400 arrobas of Melons. Now at a rough calculation these 400 arrobas weighing 10,000 lbs. may be estimated at the value of ¾d. per lb., which is equivalent to about £32. This calculation will give a slight idea of the importance of the Melon trade. To form an idea of the wealth of Spanish irrigated ground we must remember that four crops annually are raised upon the same plot; and that growing amid Melon or Apricot grounds stand the Peach, the Fig, the Pomegranate, or the Almond tree.

— *BROWNEA GRANDIFLORA* has, says the *Irish Farmers' Gazette*, been for some time in flower in the large stove at Glasnevin, and the noble tree, for such it is, of B. grandiflora in the same house is just now showing for flower, and a magnificent display may be confidently looked for by-and-by. In the same department a lofty and well-furnished tree of the Mango is flowering freely, we trust to be followed by a good set and a heavy crop of this delicious tropical fruit.

MISTLETOE.

I HAVE seen the Mistletoe growing on the Apple, Pear, Plum, Cherry, Medlar, Quince, and Filbert, also on the common Oak, Ash, Elder, Maple, Black and White Thorn, Poplar, Elm, Horse Chestnut, Lime, and Laburnum.

On the Lime trees, in the park of Compton House near

Stockbridge, Hants, it may be seen in abundance. Huge bushes they are, or rather were. I have cut some myself 3 feet in diameter. Two rows of large old Lime trees each side of the carriage drive in front of the mansion were indeed grand to behold during the winter months, being literally covered from top to bottom with huge bushes bearing such an abundance of their white berries that they were plainly visible from the windows.

Adjacent to the Limes was a Laburnum tree; this stood in a shrubbery in the pleasure grounds, and on this the Mistletoe might be seen growing. Also in the orchard adjoining, on the fruit trees before mentioned, good-sized bushes might be seen, but nowhere was it so luxuriant as on the Limes. All the trees in my list were growing on the same estate.

I can vouch for the above facts, having lived in the gardens with my late father, who was at that time gardener there.

I have never seen the Mistletoe growing in such abundance anywhere that I have lived since, with the exception of on a very old Willow tree adjoining the park of Lockerby Hall in the same county. This tree is very much decayed and broken, more from extreme age than from the parasitic growth upon it.—F. H. FROUD.

GRAFTING OLD PEAR TREES.

We have five large Pear trees in our garden, called about here "the Pine Pear." The fruit is not fit to eat, and only makes very rough perry. They are just in their prime, and bear heavy crops of fruit; but being of so little use I would sooner cut them down than leave them as they are. The fruit ripens in October and November. Would it not be worth while to try grafting? The stems are perfectly sound, and the trees show no signs of decay. Pears and Plums do very well here (Gloucester), better I think than Apples, and everything off our ground has a very good flavour. Our soil is a stiff clayey marl. What sorts would be best to graft on the trees?—G. NEWMAN.

[By all means graft your trees, and you will have abundant crops of excellent fruit in much less time than if you were to replace them with young trees. Do not confine the grafts to one or two main branches close to the stem, but secure as many lateral limbs as you can, even if you have to retain lengths of 6 feet or more for that purpose. The importance of this operation will be fully explained in the next paper on "Pears and their Culture." To have early and successive fruit take Citron des Carmes, ripening in August; Williams's Bon Chrétien, September; Comte de Lamy, October; Doyenné du Comice, November; and Knight's Monarch from December to March.—EDS.]

MISTLETOE CULTURE AT ANTWERP.

MR. VAN GEERT has obliged us by a letter from which the following is extracted:—

"The way I proceeded to form my miniature 'Mistletoe trees,' as they are rightly called, which were referred to on page 49, was simply this: I selected some well-developed berries at the end of April, and after having bruised them between the finger and thumb clefted them on the stems of some young healthy Thorns (*Crataegus oxyacantha*), placing each berry under a small twig. A month afterwards the radicle made its appearance; first straight, as if to look out where to fix, then bending itself in order to reach the bark of the Thorn. As soon as the bark was touched the point of the radicle became flat and attached to the bark of the Thorn in the same way as a leech on the skin of a patient. In this position and without any other move the seed remained till the following spring, when it lifted itself from its first position; the radicle remained cleft to the bark by its apex, became straight again, when two cotyledons formed and two small green leaves were produced. In this position the plant remained again till the following spring, when it made two little twigs each of two leaves; and as every leaf produces, the following year, a little twig of two leaves, the development of the leaves follows a geometrical progression, as—2, 4, 8, 16, 32, &c.

"As is seen by this, the development of the Mistletoe goes on very slowly at first, and that it requires at least six years before the plant makes some appearance, and this is the principal reason why I did not continue its cultivation. Another inconvenience is that in very dry weather the seeds after having germinated do not always keep alive, or after having produced their radicles and having kept well the first year,

do not the following spring produce their cotyledons, and die off."

MELOCACTUS.

THE family of Indian Figs is an extensive one, and includes some of the most curious examples of the vegetable kingdom. The genus is divided into sections—*Cactus* (Melon Thistle), *Echinocactus* (Hedgehog Thistle), *Epiphyllum* (Leaf-flowering), *Mammillaria* (Nipple-bearers), and *Melocactus* (Turk's-cap Cactus). The flowers of the first and third section are, if not long-lasting, yet singularly beautiful. Species of the other sections are cultivated for their striking forms.

Fig. 19.—Melocactus.

These plants are now rising in popularity, and those who possess good specimens do not part with them so readily as they did a few years ago. *Melocactus* may be known as having the flowers produced on a head or "cap" surmounting the plant; those on *Echinocactus* issuing from the ribs or angles; the species of *Mammillaria* being composed of an assemblage of small tubercles, and between them the flowers appear.

Their cultivation is simple. The plants requiring it should be potted in April or May in a rough compost of loam, old dried cow dung, and limy rubbish. They should then be afforded a high temperature and moist atmosphere, watering them sparingly until established, when water may be more freely applied. In the autumn they require to be gradually dried-off and be kept in a winter temperature of 45°. They require full light at all times, and are readily increased by offsets and protuberances.

COLOUR OF GARDEN WALLS.

"H. W. W." asks about the best colouring for garden walls. They are usually left of the native colour of the material of which the walls are built, and there is no better material than bricks. If there is any advantage to be derived from colour

black would be the best, as this colour would absorb and radiate more heat than any other. When Mr. Crockett was gardener at The Raith in Fifeshire, N.B., he had his Peach and Apricot walls coloured black. There did not seem to be much gained in earliness, but as the whole wall was coloured and not a portion for experiment, one could not tell whether there was any difference practically. As far as I can remember the trees were not in the best condition; for my own part I have never thought of colouring walls similar to those at The Raith, as they had not a very lively appearance. —J. DOUGLAS.

“We think Mr. Douglas is right, for dark-coloured walls become colder than light-coloured at night unless screens are then put before them. We extract the following from “The Science and Practice of Gardening :”—

“Colour has a very considerable influence over a body's power of absorbing heat. If a thermometer on a hot summer's day be exposed to the sun, it will indicate a temperature of about 100°; but if the bulb be blackened with Indian ink or the smoke of a candle, it will rise from 10° to 20° higher. The reason for this is that the polished surface of the glass reflects some of the sun's rays, but the blackened surface absorbs them all. Blue absorbs all but the blue rays; red all but the red; green and yellow all but those of their own name; and white reflects all the rays. The lightest-coloured rays are the most heating; therefore light-coloured walls, but especially white, are the worst for fruit trees. The thermometer against a wall rendered black by coal tar rises 5° higher in the sunshine than the same instrument suspended against a red-brick structure of the same thickness; nor will it cool lower at night though its radiating power is increased by the increased darkness of its colour if a proper screen be then employed.”]

NOTES FROM MY GARDEN IN 1875.

FRUIT.

I AM not a fruitist, and yet I like to think that I have fruit in my garden, and am curious in noting some of the climatic effects on the little I have from year to year, to mark the failures and chronicle the successes; and as my garden may resemble many others it may not be uninteresting to some of our readers if I make these notes public. I aspire to no superiority in culture, no great extent of knowledge, and to nothing exceptional in what I cultivate, yet I may interest some.

I have mentioned that I had a small miniature fruit garden which I owed to the kindness of Mr. Rivers. In the autumn of 1874 I moved a row of bush Plums to give the Pears and Apples more room, and placed them at the bottom of my garden where the soil is stiffer than in that part where they were. They had never borne anything worth mentioning in their former position, but last season I had a capital crop, especially on some trees. Of Plums Pershore was very full, and pronounced by all as one of the very best kinds for preserving, quite equalling Green Gage and better in colour. Oullin's Gage was also very good. I had a few Jefferson's of good quality also. The success which has attended this removal has induced me to do the same with the small Apples and Pears, which I have this autumn transferred to other quarters. But Cherries I must away with. They have borne a few, but the blackbirds always get them, and I do not see the use of filling up my garden for their benefit, while to cover them up would cost more than they are worth in this county of Cherries. I have already mentioned what a disappointment this crop was last season. There is but one large Bigarreau tree in this garden, and it is not by any means in a good position, but bears tolerably well. Last year it was fully laden, but the dreadful wet, day after day, so completely spoiled the fruit and washed out all their flavour that they were really not worth gathering.

There is one matter on the subject of Pears I cannot understand. I have already mentioned that I was obliged to cut down a tree of Knight's Monarch because the fruit never would ripen. I have against the only piece of wall there was here until lately a tree of Beurré Diel. It bears well, and the fruit is large and handsome, but I have them now (January 29th) still unripened. They have turned quite yellow, and anyone looking at them would say that they are ripe; but they are hard and neither “beurré” or “demi-beurré,” and they have at last been handed over to the cook for stewing. I asked “our doctor” about them, and he advised their being put into a warm place. This was done, but still they would not ripen. My neighbour has a tree of the same sort, and it ripens its

fruit well. Am I to attribute this to some defect of the soil? Have any of our readers found that the soil affects this variety in this manner, and that, like Knight's Monarch, it requires something stiffer? I have (being highly convinced of its excellence) added Doyenné de Comice to the few already here, one on the wall and two as pyramids. The growth seems to be robust, and no one who has tasted it when well grown can fail to be satisfied by its flavour. There was a wonderful crop of Bon Chrétien and Beurré de Capiaumont on my two large trees. Comte de Lamy was not as full as last year, but for an October Pear I know nothing to beat it. It has for the eight years that I have been here usually borne well, sometimes enormously, and its flavour is of the very best.

In Apples I have at last succeeded in procuring a couple of trees of a very old favourite sort of mine—the Irish Peach, not as well known as it ought to be. For an August fruit there is not one that I know of to equal it when gathered from the tree. There is another Apple of Irish origin better known which follows it—the Kerry Pippin, a briar and delicious fruit. Amongst the large trees here is one of a variety which I believe to be the Forge or Gough Apple; for although I have frequently taken samples of it to be named I can attain no certainty about it. It is a very abundant bearer and an excellent cooking Apple, and has the peculiarity of fruiting every second year; and thus, although this was all around us a very good Apple year, I had not a single fruit on it. Last year was not a good year, but still it produced a few bushels. Cox's Orange Pippin is, take it all in all, about the best Apple for early winter that we have, and I have grafted it on a couple of trees that did not produce well. Some fruit that Mr. Dancer of Chiswick was good enough to send me were splendid in appearance and flavour.

Strawberries were not a great success. I had (for the last time, I am sorry to say) a nice crop in the house, but out of doors they were neither so fine or plentiful as usual. The only variety of any novelty that I have tried was La Groesse Sucrée; it seems to be a useful early kind, free-bearing, and of good flavour. It does not seem, however, that we are improving much in this delicious fruit; and it would, perhaps, be hardly possible to conceive any great improvement on some of the old-established kinds, unless we could obtain sorts that would prolong the season. The earlier sorts are quite as early as we hope to find suitable for our uncertain climate, but it would be a great boon if we could have some that would come in even later than Frogmore Late Pine, Elton, or Eleanor.

But if Strawberries were not a success Raspberries were. From my few short rows I gathered more than 150 lbs. of fruit of fine quality. And here let me say that I thoroughly believe in the plan I have adopted. They are planted in a cool place in rows; a stout galvanised wire is stretched along and the canes tied to it. The soil is never dug, only forked over and manured well, and the canes are something remarkable.

My Fig trees did not produce anything like the quantity of fruit which they did in 1874, nor was the fruit of such good quality; but this I attribute, not to any failure in the trees, but to the unpropitious character of the season, more especially the want of sunlight in which the Fig rejoices. For the same reason all about here the outdoor Grapes which are grown on many cottage walls were also a failure. Indeed they have been so grievously attacked with mildew that I question very much whether they will recover it.

I have said nothing about wall fruit, for in truth my wall trees are in their infancy. Last year was an unfavourable one for planting and maturing young wood. I know nothing about them, and fully expect mine are all wrong. Unfortunately I have no one about here whom I can ask to look at them for me, and so they must take their chance. Mr. Baines was kind enough to give me a lesson the other night at the Horticultural Club and I have gone on that; but I rather fancy the trees were not very shapable when I received them, and so if they are very bad I shall have some excuse to fall back upon.

I do not think I should have ventured to write thus of my little belongings, but that many have expressed to me their satisfaction with my notes of former years, and that I myself have benefited by some such similar notes from others.—D., Deal.

THUNBERGIA HARRISSII.

THIS is seldom met with, but when well grown it ranks amongst our best flowering evergreen stove climbers. It is of easy growth; and when in bloom, at this time of year, besides

adding to the beauty of the house in which it is grown, it assists in helping to fill the out-flower basket at this dull and difficult time to get a good quantity of flowers. When cut and sent in the blooms have been taken for Gloxinias: this alone will show how pretty they are. It is amongst the cleanest inmates of the stove, its greatest enemy being red spider; but by proper drainage and liberal supplies of water when growing freely, with daily syringings, this pest can be easily kept in check if not entirely prevented. Like most other climbers it grows better and makes larger plants when it can be planted out in a prepared border having ample drainage, with a compost of rough fibry loam, leaf mould, and a little sand and charcoal, all well mixed together. Having a naked piece of wall at the north side of our plant stove, on the top of which rest the glass lights, we covered this wall with *Lycopodium denticulatum* by making a network to hold about 10 inches wide of rough loam and leaf mould, and pricking the *Lycopodium* all over. I have planted *Thunbergia Harrissii* on the top, along with several other creepers, and trained them to wires run across the house, about 6 inches from the glass, and they have done well: some of them are in flower now, such as *Ipomoea Horsfallii*, *Thunbergia*, and *Euphorbia Jacquiniiflora*. This does well, and throws large spikes of bloom. The graceful creeping Fern, *Lygodium scandens*, runs up the wires; and when trained carefully can easily be cut off in long pieces, for drooping gracefully from epergnes.—A. H. —(The Gardener.)

CHAPTERS ON INSECTS FOR GARDENERS.

No. 5.

My good friend Jones was considerably discomfited the other day when I let him into a new fact concerning the details of fly history. It is observable with most persons that they cling closely to the beliefs about natural history which they acquired in boyhood, erroneous as these must often be; and so my friend held it as "next to gospel" that all flies can do in their perfect state is to suck honey or other fluids by means of a proboscis. I assured him that many of these flower-loving flies have a capacity for doing something more than this, being, in truth, provided with vigorous maxillæ or jaws, by means of which they masticate the pollen of flowers. It is not easy, obviously, to watch and catch flies in the very act, but dissection has disclosed in the internal structures of some of these species a compact mass of undigested pollen. The case is therefore as clear against these predators, if so they are to be spoken of, as when a pickpocket is caught in a crowd with a watch in his hand which does not belong to him. But as these flies do not merely eat the pollen, since they serve also as media for its conveyance from flower to flower, their position as agents in fertilisation evidently requires us to regard this fact in their economy with favour rather than with the reverse feeling. Jones certainly—these circumstances having been made clear to him—did admit that Nature produced, amongst a host of species, more pollen than was actually required, favouring thus the hypothesis that it is intended partly to serve as food for other creatures; still he didn't like the idea of this wholesale transference of pollen by winged insects, seeing that, as he lucidly put it, "species might get mixed up everywhere by-and-by." Against this view I could well urge that flies have doubtless had the same habits they now have for many centuries; therefore apprehensions about a general fusing of species in a genus or order are needless.

To resume, however, at the point where we paused in the last paper, we pass from the little *Cecidomyiidae* to their next of kin, the *Bibionidae*, insects not quite so slim and slender, yet gnatlike in appearance and mode of flight. It is only necessary to name *B. Marci* (strangely called also "St. Mark's Fly") to remind the gardener of an unpleasant enemy in this family, which shows itself by its effects both in the flower garden and also among Strawberry beds, the small hairy grubs devouring the roots of plants. Occasionally they muster in companies, and then necessarily the injurious effects are more marked. The fly itself has a curious "phiz" in the male specimens, the front of the head appearing as if it were occupied by one large eye. On a closer inspection we perceive the organs are separated by a narrow line; the female insects, however, have the eyes rather small. Others of the *Bibionidae* have subterranean larvæ, feeding promiscuously on the roots of grasses and various plants, and some feed on decaying matter such as dung or vegetable refuse, and therefore to a small extent they are of use. On the whole the *Bibionidae*

occupy a neutral position, though a few species are to be ranked with the enemies of the horticulturist. The imago, or perfect fly, in this group has no partiality for flowers.

A passing word is all we need bestow on the small family of the *Simuliidae*, curious to the naturalist because the aquatic larvæ spin a cocoon for their pupation, by which the insect is only partially protected from the action of the water. The flies are distinguished by the peculiar broad and flattened aspect of the tibia and the first joint of the tarsus—that is to say, of the shank of the leg and the first joint of the foot. In northern regions the familiar term for these insects is "Sand-flies;" in warmer latitudes they share the appellation "Mosquito" with the *Culicidae*, the Mosquitoes proper. In Britain the Sandflies are not numerous enough to be specially troublesome, nor do they bother the gardener more than any other man.

As much might almost be said of the large family of the *Midges*, numerous in species, numerous also in individuals. These have slender legs, which are not flattened, and we distinguish them from the true gnats by the costal vein or ray, which is continued along the tip of the wing amongst the gnats, while it ends before it reaches the tip in the tribe of the midges. Nearly the whole of the larvæ are aquatic. The slim red maggot known as the bloodworm is a familiar example. One or two species have larvæ making their habitations in moist dung; and one species at least, probably ranking in this family, the Pear Midge (*Sciara Pyri*) infests our orchards, the larvæ burrowing into the ripe fruit of the Pear and causing its downfall; but it hardly stands out as a prominent foe of the Pear, though it is sufficiently unpleasant to bite into a fruit that contains a long track filled with the frass of this larva. Many of these midges have the antennæ beautifully feathered, the adornments, as with the gnats, being strictly masculine; the feminine antennæ are, with scarcely an exception, straight and simple. Also, like the gnats, the midges have a propensity for attacking the skin, though some species are quite harmless, and on the whole they occasion little annoyance compared with the *Culicidae*. I would not advise any horticulturist to rest his faith upon the popular belief that when a company of midges are seen performing their aerial, and certainly graceful, evolutions at the witching hour of twilight it is a prognostic of an approaching fine day. It is at least an indication that at the particular moment a calm prevails, for these flies do not care to face a breeze, but they will sometimes be out on the wing when it is actually raining, and dexterously dodge raindrops one of which would carry a midge to the ground. Some gardeners, I fancy, have a dislike to these flights of midges, supposing that when they occur in gardens, as they frequently do, they attract insect-eating birds to the spot, and induce the birds, if their hunger is not sated, to attack buds or flowers. I hardly see any good reason for this apprehension, nor for any similar fear in the instance of the true gnats.—J. R. S. C.

ROYAL HORTICULTURAL SOCIETY.

A VERY interesting and faithful account of the rise and progress of the Royal Horticultural Society from the pen of Mr. W. A. Lindsay appears this month in "St. James's Magazine." Mr. Lindsay was for some time Secretary of the Society, and had every opportunity of making himself acquainted with everything connected with its past and present history by reference to documents and other means at his command, and the way in which he has performed his self-assigned task is most creditable to him. The origin of the Society is thus given:—

"On April 17th, 1809, was granted a charter incorporating the Horticultural Society. The Earl of Dartmouth was created President, Mr. Charles Greville Treasurer, and Mr. Richard Salisbury Secretary. The members of the first Council were the Earl of Powis, the Bishop of Winchester, Lord Selkirk, Sir Joseph Banks, Messrs. Acton, Elliot, Knight, Miller, Trevelyan, Dickson, Hoy, and Smith. Three members were to retire at each annual meeting, and to be replaced by others. Between 1804 and 1809 a gradual increase of members had taken place. The grant of premiums had had the most beneficial effects on practical horticulturists, and patronage only was required to insure success. The publication of the "Transactions" in the form of volumes began in 1812, and it may here be stated that the total number of these volumes cost the Society no less a sum than £80,000. They were without doubt a powerful means of attracting support, and are still of considerable literary value.

"At this period of its existence the Society paid the modest sum of twenty-five guineas a-year to the Linnean Society for a share of their accommodation in Gerrard Street, thus commencing a friendship between the two bodies which has always continued to subsist."

From this we learn the composite form of the new Council—a form which it has been too much the practice in later times to ignore. In the original charter James Dickson, Thomas Hoy, and William Smith are styled "gardeners." Aiton (not Aston) was the gardener at Kew, Miller was the son of old Philip Miller of the Botanic Garden at Chelsea, Smith was gardener to Lord Liverpool, and Hoy was gardener to the Duke of Northumberland at Syon. Now the effort is to keep practical men off the Council, and we have no doubt that this is one element in the failure of the Society's endeavours to advance horticulture at the present time.

Mr. Lindsay proceeds—

"In 1811 Mr. Knight succeeded, on the death of the Earl of Dartmouth, to the presidency. He retained the post until his own decease twenty-seven years later. A large portion of the Society's more valuable work was thus performed under his guidance, and is now bound up with his memory. But in 1811 and following years the causes which impeded the early progress of the Society increased in force. Europe was the scene of universal war, and England continued to be the principal European power in arms against France. At such a time, and amid the popular excitement in which all classes of society were involved, little progress could be looked for in such an enterprise. Elections were few, but a careful Council kept the expenditure within the income, and each year added a small sum to the Society's balance. This amounted to £258 in 1815, when the return of peace restored the thoughts of the people to legitimate channels. The labours of the Horticultural Society had entitled it to be considered as one of the most useful institutions, and all things thus tended to the approach of prosperity. In May, 1816, there were invested in the Three per Cents. £1000. Elections took place with greater frequency, and in 1818 the income was £1,791 and the expenditure £1,713, while the funded property was £1,400, and the value of the stock £3,000 in excess of all debts. An experimental garden was now established at Kensington and a nursery at Ealing. A house in Regent Street was bought in 1820 for £4,200, and although the subscriptions were raised from two to three guineas, new Fellows poured in at the rate of two or three hundred a-year."

A long run of prosperity followed, and the Society was enabled to send out collectors whose names shed a lustre upon it which even yet remains. Forbes, Parks, Don, Douglas, Hartweg (whom Mr. Lindsay omits), and Fortune are names that will live as long as horticulture exists. Mr. Lindsay is in error in placing Mr. Reeves among the Society's collectors and the predecessor of George Don. Mr. Reeves was a gentleman who held an appointment under the old East India Company and merely acted as the Society's correspondent; but to him the country is indebted for some of the most popular and ornamental of its garden plants. The *Glycine sinensis* and the Chinese Primrose are alone sufficient to keep his memory fresh in the minds of all lovers of the beautiful. To his son, Mr. John Russell Reeves, who was lately a member of the Council, the Society and the country are equally indebted for many valuable introductions. But evil days began to dawn, and, says Mr. Lindsay, "the Society now began to experience reverses."

"An officer absconded with a large sum of money, and a feeling of distrust for the management resulted. A further cause of dissatisfaction was the abandonment of an annual dinner and the substitution of public breakfasts, thus inviting fashionable support rather than attempting to maintain and stimulate that *esprit de corps* which is so essential to all public bodies. The breakfasts were abandoned in 1831, and were succeeded on the suggestion of Dr. Lindley—the Assistant Secretary and well-known botanist—by garden exhibitions. These became exceedingly popular, and retained public favour for a long period of time. Nevertheless the financial position was most critical. A committee of inquiry was appointed in 1830, which reported that the debts amounted to £30,243 and that the value of the property was but £16,500. The cost of the garden works had exceeded the sum subscribed for them by £29,000. The management was condemned, and in consequence Mr. Sabine resigned the secretaryship, to be succeeded by Mr. Bentham. A determined attempt was made to retrieve the Society's position, but it was considered of paramount importance to maintain the scientific work. Between 1830 and 1855, in addition to the money allotted to the payment of debt, £11,000 was spent on the garden, and £7,000 on foreign importations.

"Notwithstanding the enthusiasm which all these labours and

successes must have stimulated, the Society was much hampered as all such bodies are by the non-payment of subscriptions. No less a sum than £12,879 had to be abandoned as irrecoverable between 1824 and 1855. Had it not been for this unhandsome conduct, it may be doubted whether any serious debt would ever have been incurred. At no time since 1828 had the liabilities exceeded £14,331, and at the period of which we are speaking the total debt had been reduced to £9,986."

The exhibitions now began to fall through competition of rival societies nearer town; the house in Regent Street and the valuable library were sold to pay liabilities, and—

"an office was then acquired in St. Martin's Place, Trafalgar Square, at a rental of £80 a-year. The effect of these changes was not merely to reduce the annual expenditure, but to bring down the liabilities to £4,694, as against a floating property valued in 1857 at £14,674."

The Society was, therefore, not in the straits which some are so fond of representing it to have been. A debt of £4,694 as compared with the £55,000 it now owes is but a small affair, and we commend this to the attention of gentlemen who at the annual meetings find great delight in telling the Fellows of the abject state of the Society when the Royal Commissioners so benevolently took it by the hand.

Since that period the career of the Society has been one of signal failure, notwithstanding every attempt to place it on a prosperous basis. How has this arisen? The answer is not far to seek. It is simply because a grand scheme to supply entertainment to the residents of a fashionable suburb of London is incompatible with the placid pursuits of horticulture. To maintain an establishment permanently, such as that which it has been sought to set up at South Kensington, subject to the influence of the caprice of fashion, is an impossibility. It must have its vicissitudes, as all such places have, and its fortunes must follow those of every place where the cost of their construction has been so enormous that no reasonable amount of income can possibly make them financially successful.

The Society is now passing through a crisis, whether it is for the better or the worse only time can tell; but of this we are perfectly certain, that so long as this state of things continues it is a misnomer to call it a Horticultural Society, and a fallacy to suppose that any good can arise to horticulture by maintaining it in its present deplorable condition.

We commend Mr. Lindsay's paper to the careful attention of all who are interested in the Society's welfare.

OUR BORDER FLOWERS—MONKEY FLOWER.

Musk is a universal favourite. It is a plant that will exist almost under any circumstances, provided it can have light, air, and moisture. Especially among our humble friends Musk is enjoyed, and to hear what enjoyment their little floral pets afford them is a great satisfaction, and who would desire their pleasure to be less? Musk, in addition to its perfume, is an obliging subject—at home alike in garret, cell, or palace. It flourishes in sunshine and shade, and is not over-particular as to soil. We will now leave *Mimulus moschatus*, and glance at some others of the family, which embrace colours that no other flowers can approach.

The *Mimulus cardinalis* section require a good rich soil to develop themselves. They are moisture-loving plants, yet should be provided with efficient drainage, and then water cannot be too freely given them. They may be increased by seed and division at any time. *M. cardinalis* was at one time looked upon with favour as a pot plant. *M. atrosanguineus* is a grand acquisition to our border flowers, and is a useful plant when well-grown for indoor decoration. It is well adapted for exhibition purposes as an herbaceous plant, and continues in bloom a very long time. *M. cupreus* should be in every garden. It is of very dwarf habit, producing its flowers in great abundance; though the individual blooms are short-lived the plant gives a continuous succession of flowers for a long time.

M. Moodii, *M. maculosus*, *M. Youngii*, *M. tigrisoides*, to say nothing of *M. inimitabilis* flore-pleno, are all very desirable for winter and spring decoration indoors, and for borders in summer. By liberal treatment the plants may be grown to a large size, and when coming into bloom they should be placed in pans of water an inch deep. They are all the better for having weak liquid manure occasionally, for if they are not

kept growing freely they soon become infested with green fly. When under glass they should have thorough ventilation. They are all easily increased by seeds and division.—*VERITAS.*

THE ELM.

SOME writers think that the Elm (*Ulmus campestris*) is not a native of this country, but they have no reasonable grounds on which to found such an opinion. The name Elm is Anglo-Saxon, and appears to be derived from a root-word indicating height and strength. As corroborative evidence, justly cited by Dr. Hunter are nearly forty places in England, mostly mentioned in Domesday Book, which have their names compounded with the name of Elm.

Whenever any plant has associated with the times of its leafing or flowering the seasons for performing garden operations, that is a certain indication that the plant was in England, as lawyers say, "before the memory of man runneth to the contrary." The Elm is one of those guide plants accepted by gardeners in the olden time, and they had this rhymed kalendariol warning:—

"When Elm leaves are as big
as a shilling
Plant Kidney Beans if to plant
'em you're willing.
When Elm leaves are as big as
a penny
You must plant Kidney Beans
if you mean to have any."

Nor were our countrymen the earliest to deduct indications from those leaves, for Virgil wrote that

"Each trembling leaf with
some light vision teems."

Miller states that "Queen Elizabeth is said to have planted an Elm with her own hand at Chelsea. It went by her name, and I remember it a stately flourishing tree, except that the top was decayed. It stood at the upper end of the church, and marked the boundary of the parish on the north side. It was felled on the 11th of November, 1745, and sold for a guinea to Sir Hans Sloane, Bart., lord of the manor. It was 18 feet in circumference at the bottom, and 110 feet high." But Gilpin tells of one far larger that was felled in 1674 on Sir Walter Bagot's Staffordshire estate. Two men were five days in felling it. It was 120 feet high, the stool 47 feet in circumference; 160 naves for wheels, and 8660 feet of boards were cut from it, and the whole tree was computed to weigh 97 tons.

No tree is better adapted for the formation of an avenue, and not one is more used for the purpose. The most striking example we remember is that at Strathfieldsaye, a mile in length. The fitness of Elms for avenues arises from their branches crossing at a pleasing angle, growing pendant in age, and far above the heads of the passers beneath. Gilpin truly observes that no tree is better adapted to receive grand

masses of light, nor is its foliage, shadowing as it is, heavy in effect. Its leaves are small, commonly hang loosely, and the forms picturesque. It is the first tree that salutes the spring with its light and cheerful green, a tint contrasting agreeably with that of the Oak, the early leaf of which has usually an olive cast. In autumn also the yellow leaf of the Elm mixes as kindly with the orange of the Beech, the ochre of the Oak, and other hues of the fading wood.

It was of the common Elm that Hood sang—

"The tall abounding Elm
that grows
In hedgerows up and down,
In field and homestead, grove
and park,
And in the peopled town;
With colonies of noisy rooks
That nestle in its crown."

These lines are faithfully descriptive of this Elm, for as a park, hedgerow, and homestead tree it is very familiar, and few trees are more imposing. It is also true that the rooks have a great partiality to the Elm, and it is of its twigs principally that they build their nests. It is not, however, a tree well adapted to the "peopled town." In the country it is majestic as the avenue noticed, and the grand trees at Windsor and other places attest, but in smoky towns Elms are seldom long-lived, and furthermore their peculiarity of suddenly parting with limbs in storm or in calm render them unsafe. It is a singular fact, and not clearly accounted for, that in calm, still, sultry days the huge branches are prone to fall with a crash without a note of warning. On that account it is not suitable for towns, nor yet for village greens where "men do congregate." The Plane is the tree of trees for towns, and for village greens the Chestnut is of free growth, and affords luxurious shade. Who can think of planting village trees without calling to mind the rural warblings of Longfellow in the well-known song—nay, is it not a hymn?

"Under the spreading Chestnut
tree the village smithy
stands."

Fig. 80.—*ULMUS CAMPESTRIS.*

Our advice is, therefore, that Elms be planted only in parks, hedgerows, or avenues in rural districts, and not in towns or villages.

That only applies to the subject of our illustration, for there are other varieties of the Elm singularly ornamental and perfectly safe. Drooping Elms are particularly effective as lawn trees. They are quick growers, and their outline is graceful, speedily forming natural bowers if a little care is taken to train their pendant branches; and the gold and silver variegated sorts afford a fine relief to the dense greenery pervading landscape masses.

U. campestris and its allies are raised by suckers and layers, but chiefly by seeds, which should be gathered in June as soon as ripe, and sowed in light mellow soil. The ornamental varieties are mostly grafted on stocks of *U. montana*. The

trees of all the family may be successfully transplanted even after they have attained to a considerable size, their fibrous roots becoming speedily re-established in fresh soil.

BEGONIAS FOR SUMMER AND WINTER.

ATTENTION has been prominently directed to the new varieties of the tuberous-rooted section of Begonias, and their great value as summer decorative plants has been pointed out. I admit their great usefulness, indeed they may be regarded as indispensable for summer decorative purposes; but I would not have some of our old favourites neglected, and especially the species that bloom throughout the winter and spring months. Where cut flowers are in great request, and where heat is provided, Begonias should be cultivated freely, for they afford an unfailing supply of elegant sprays. For this purpose some of the old summer-flowering species and varieties are extremely useful, as *parvifolia*, *Digwelliana*, *Weltoniensis*, *semperflorens*, &c., while *B. Pearcei* (tuberous), for beauty of foliage and flower combined, is surpassed by few stove plants. *B. Pearcei* is best raised from seed; the seedlings making beautiful plants, which flower the first season. The others should be increased by cuttings. All of them are extremely useful, and of the easiest culture.

But I would draw attention more particularly to the useful old sorts which flower in winter. For many years I have had to meet large demands for cut flowers, and without these Begonias I could not have succeeded in supplying these demands. Not only their soft quiet colours, but the profusion of their flowers, and the elegance of their sprays, have been found invaluable for many purposes of decoration.

B. semperflorens is appropriately named, for it is ever blooming, and in winter is very valuable; even more so is its variety *semperflorens Saundersii*. The flowers of this are white, upright, and having compact trusses. They are singularly effective associated with the bright glossy foliage of the plant where arranged with other cut flowers. The plant is of dwarf and compact habit; and arranged with Ferns is, in the winter especially, highly ornamental.

B. insignis (Showy), is a very old favourite, and it also is appropriately named, for its massive yet elegant semi-pendant trusses are indeed striking. It is one of the most useful of winter-flowering stove plants, and will afford unlimited supplies of cut flowers from October till May. The plants also are exceedingly ornamental, and besides their intrinsic beauty set off to greater advantage such high-coloured plants as *Poinsettias*. A combination of these plants with Maiden-hair Ferns cannot fail to be admired.

B. fuchsoides is another species of great value. Its coral-like pendant flowers are almost unequalled for forming a drooping fringe from the margins of epergnes and other table ornaments, and especially when viewed by artificial light. The plants are also attractive in the stove, especially when grown on single stems, showing themselves above their neighbours, which they do with effect, and without doing injury to the plants beneath. Placed at intervals near the margin on both sides of a stage, and trained to arch over the pathway, their points meeting overhead, they form a distinct and pleasing feature in the arrangement—free, elegant, and bright. Plants of a foot high flower most freely in thumb pots. I have so grown them by hundreds for turning out of their pots, and furnishing fringes to sides of hanging baskets in the conservatory and boudoir.

B. manicata is another fine old plant when well grown, flowering in spring. The massive habit of the plant, and the large foliage, being surmounted by spikes containing thousands of delicate flowers, resembling a cloud by their airy lightness and elegance.

B. nitida is also eminently worthy of culture, and in the depth of winter will produce trusses of bloom not much inferior to those of *Hydrangeas*. These old-fashioned plants are real gardener's friends if treated in a friendly manner. They require heat, and, this being provided, their culture is exceedingly simple.

The plants flower best when young, and they should be renewed by cuttings annually, the cuttings being inserted at the present time if large plants are required. Smaller flowering plants may be had for special purposes by striking the cuttings any time during the summer. Loam, leaf mould, and peat will grow them well, the last shift being into rich loam. They should be grown near the glass in the stove until June, when frames heated by the sun will be suitable for them until

September, when they must be replaced in the heated structure, and they will produce their flowers freely for fully six months.

These good old plants are not cultivated so well and extensively as their merits deserve. I cannot conceive how the full winter supply of cut flowers can be produced without them, and therefore I call attention to them at a seasonable time for raising a supply of plants, as supplemental to the useful articles which have recently appeared on the more modern type of summer-flowering varieties.—A NORTHERN GARDENER.

PRUNING ROSES.

[We publish the following letter from a correspondent, with a reply from one of our contributors, as it opens the whole question of pruning Roses.]

As you have sent me a query from "E. P. B." as to the proper method of pruning Roses on the Manetti stock, and as the question is one of great importance to Rose-growers, I ask you to publish the letter with the following answer which I venture to send; at the same time I am obliged to confess that with the present very fickle and uncertain season it is difficult to give definite advice.

"I shall be obliged for advice as to pruning my Roses. They are all dwarfs on Manetti stocks. They are in three lots. No. 1, planted last year and untouched. No. 2, plants planted here November, 1874, moved January, 1876. They were moved direct from their former quarters; about half an hour out of the ground. No. 3, a lot from a nursery received last week.

"State of different lots—No. 1 now making strong shoots. No. 2 shooting out, but not so strong as No. 1. No. 3 the usual nursery stock, but very strong. No shoots pushing. The aspect is E.S.E. When are they to be pruned, and how? Some say the lower you cut them the better. I dread cutting a bare stick for fear of no shoot resulting. Tell me when I am to prune them, and to what extent (they are all H.P.'s). I pruned No. 1 lot last year in February. It was the worst season for Roses that I can remember—cold, wet. The young shoots were first cut up by the dry parching weather in April, and the poor blooms washed out by the subsequent rains. Despite the weather I had magnificent blooms on Abbé Brammer (which, by the way I do not see among the chosen in the *Journal of Horticulture*), Annie Wood, and Alfred Colomb. These three seemed to disregard weather. The elevation here is 450 feet, and now, though we have had some frost, the Tartarian Honeysuckle is in leaf and the Mezereon in flower. It is not easy to know how to manage in such variations of temperature.—E. P. B., Co. Dublin."

Here there are three classes of Roses to deal with, but I presume all are on the Manetti stock. The first planted last year and untouched. I am obliged to ask, Untouched this year, or untouched from their first planting? If never pruned at all they may have been very materially injured; if it only means that they have not been pruned since their first growth I would say, Do not be afraid of the knife; in fact, I should give the same advice in both cases, but should fear if they never were pruned since first planted that they will not break kindly now; still as they are on the Manetti it is far better to cut well back, thin-out very weak shoots altogether, and do not be afraid even if you see no eye at the base; if only the plants have made good roots they will be sure to push.

No. 2, plants put out in November, 1874, and moved this January. As the season is forward and they have been moved carefully they are not likely to have received much check. I should recommend you to leave them for ten days or a fortnight longer, or about the middle of February, and then prune as you would have done if you had not transplanted, but rather more severely. Out out all weak wood; prune the strong to five or six eyes, the medium to three or four.

Next, No. 3, as to new nursery stock. Plant them as they are, or rather, if you have planted them, leave them as they are till the season has further advanced. If the weather continues open there will be an inclination to form roots, but new buds will not be formed for some little time, probably not till the middle of March; but about the second or third week in March prune back severely, the weaker shoots remove altogether, the stronger prune to three or four eyes. I know some will say I am recommending a severe measure, but experience has convinced me that "spare the rod and spoil the child" is an adage true with regard to Roses, and in some cases, if not most, utterly fallacious as regards the child. Roses will answer under severe treatment, but children seldom.

Some persons say no amateur ought to prune his own Roses, as they do not like to cut away promising buds. There are exceptions to all rules. Thinning-out and removing all old and weak wood is, on the whole, more important than pruning-back strong wood; in fact, last year I left some La France Roses, which began to push early, quite unpruned, and I had some remarkably fine blooms from them, but then the growth was strong, and there were no feeble shoots.

Roses on Manetti bear cutting-back far more than standards, because the object is not so much to produce symmetrical heads as to obtain good blooms. As a rule, so long as the Manetti stocks have good root-hold no one need be afraid of cutting-back too severely. I have had my Roses too often cut down by frost to the snow line, and make all their growth from apparently barren eyes or below the ground, ever to be afraid of severe pruning. Last year, for instance, the frost of December 31st, 1874, and January 1st, 1875, killed my Céline Forestier in every case down to the ground, but I never saw much more vigorous growth than every plant made. Many others were severely injured, but, with rare exceptions, all Roses pushed vigorous shoots from below the snow line.

I can fully appreciate your correspondent's admiration of Alfred Colomb and Annie Wood. They are two really first-class Roses, though Alfred Colomb is the most certain and best opener. Still, Annie Wood is not far behind, but Abbé Brammerel will, I fear, disappoint him on second trial. The petals are coarse and rough, and the outline uncertain, though it may eventually prove a better garden Rose than I give it credit for. It will never earn many laurels on the exhibition-table.

This winter which has shipwrecked many weather prophets who ventured to predict an arctic winter of unexampled severity, will, I fear, be likely to prove a treacherous one, and unless we have a backward February and March, spring flowers will be too forward, and fruit blossoms will have to contend against the uncertain weather of April and May. With us in Yorkshire the last week in May is too often the one which plays havoc with fruit prospects. I have known even in the midland counties Potatoes with young tubers fit for the table cut down and blackened with a single night's frost the first week in June.

Ireland may be free from these sudden variations; still it is better to try and guard against them by pruning-back sufficiently so as to prevent the early growth at the end of unpruned shoots being relied upon for blooms. Apparently this year the Continent is bearing the brunt of the winter, and the south of England—south of the Trent—has been colder than the north, the average of Stornoway far warmer than Paris, and Valencia in Ireland warmer than Biarritz.—C. P. P.

WAB WITH INSECTS—VENTILATION.

Most willingly do I confirm what Mr. Taylor has stated on page 86, that the best antidote or preventive against insects is careful ventilation, low night temperature, and a moist genial atmosphere. Under such conditions red spider and other pests are comparatively innocuous, for the plants or Vines which they attack are, under the above conditions, rendered invulnerable by the stoutness of their healthy foliage.

It is possible that some situations are more favourable than others to the increase of red spider, yet I think that the practice referred to would keep it outside the houses.

I have grown Vines in a dry district for many years, and on the border adjoining the vineries I have seen the French Beans literally devoured with spider, but I am not conscious of ever seeing an insect on the Vines or on the plants, including French Beans, in the vinery, yet I seldom syringed the Vines, but treated them precisely as detailed by Mr. Taylor.

A night temperature of 50° to 55° by fire heat, followed by a day temperature of 90° by sun heat, with proportionate moisture, were the conditions that I preferred. The Vines had then a good "grow" by day and a good "rest" at night, and were kept healthy and clean.

Of vital importance is early ventilation. If the admission of air is unduly delayed no amount of opening the lights will prevent the thermometer from rising to unpleasantly high figures.

As an example of the power of early ventilation I may quote a circumstance which bears on this matter. My neighbour erected a vinery at considerable cost, but was very uncomfortable as to its being insufficiently ventilated. It was not possible, he said, even by opening the lights and doors, to keep

the thermometer below 120°. I visited his house, and found that with the fullest admission of air the thermometer was really at 110°. Suspecting the reason I requested the owner to meet me at 5 A.M. the next morning. We found the thermometer at 62°. I at once slightly opened the lights, and as the temperature showed signs of rising I opened them further. At six o'clock it was 63°, at seven 65°, at eight 68°, at nine 75°, at ten 79°, at eleven 81°, at twelve 84°, at one o'clock 86°, and at two o'clock at 89°. It did not rise beyond that until the house was finally closed, when, with a sinking sun, it was designedly permitted to rise to 93°, with every part moist.

The thermometer outdoors was 2° higher than on the day preceding and when with the doors open the vinery was at 110°, but now during a hotter day, by early and careful ventilation, it was kept below 90° with the doors closed.

That was a conclusive lesson, and from that day to this I have never heard the owner of the house complain of inefficient ventilation, but he has for some years produced splendid crops of Grapes, and no red spider.

The practice referred to of a high day (by sun) and a cool night temperature is but a lesson from Nature, when during the bright and often hot September days and chilly nights not only Celery and Cabbages, but Vines on walls, and Cucumbers, and Vegetable Marrows on ridges, are in their zenith of luxuriance, and literally outgrow the red spider.

I have only one boast as a gardener, and that is that I have had the charge of vineries for twenty-one years, and I have never been troubled with red spider, and have seldom syringed the Vines. Simply as avoiding even the semblance of egotism I request the Editors to withhold my name.—YORKSHIREMAN.

OLD TREES.

I AM amply compensated for venturing to write on this subject by the salutary suggestions and practical remarks which my letters have elicited, and when I find Mr. Robson regarding me as too "radical," and "WILTSHIRE RECTOR" considering me too "conservative," I accept them as good proofs that I hold no extreme opinions, and am not likely to advocate "dangerous innovations."

I have no pomological fancies—no pet theories to establish—but desire to see useful fruit culture extended, and old as well as young trees respected and tended. Miniature trees under finger-and-thumb government are beautiful, and also in a measure profitable, but to produce the tons of fruit necessary to supply the masses, the air above as well as the earth beneath must be utilised. Large trees, even if old, must not be hastily sacrificed before young trees are established, which in too many instances has been tantamount to "killing the goose laying golden eggs."

I would now refer briefly to two letters appearing on page 92. I will take the last first. "J. J., Lancashire," makes use of the expressive vernacular "buckheaded." He is a radical both in words and action, and has proved what I have proved repeatedly, that it is often more profitable to "buck-head" a tree than to uproot it, and also, as I have found, than to merely "top" it. He has made clear what I attempted to explain, and his practice is worthy of notice. "J. J." has "never before written on any subject and does not know the names" of many ornamental plants. He can, however, write clearly on useful subjects, and I for one should be glad for him to write again, not because he agrees with me, but as being able to give practical information on a matter of importance—the useful supply of hardy fruit.

I now turn to "WILTSHIRE RECTOR." Our friend is right that my loss from young trees was principally by growing too many kinds, and I mentioned it as conveying an useful lesson. Had the whole consisted of either Manx Oodlin or Dunselow's Seedling (mentioned by "J. J."), or any other approved free-bearing sort, without doubt I should have saved half of my £40 fine.

The Rector wishes, what all rectors should desire, to see useful fruit trees in cottagers' gardens. It is a most worthy wish, and I am acquainted with not a few of the clergy who have endeavoured to carry so laudable an idea into effect. From long residence in the country I have found how much cottage homesteads have been prized which contained useful fruit trees. The tenants of such have been regarded by their neighbours as either fortunate or favoured, and as being the holders of prizes. Such tenants seldom emigrate or clamour for reform. Fruit trees are magnets binding a man to his home, and if that home is one which he cherishes, he will

strive to make himself worthy of its possession, lest a more worthy man should be appointed to reign in his stead. I was once "one of them," and know what it has been to trudge eight miles a day, and work with them for 2s., therefore I know their views, and that I speak the truth on this matter.

I also know something else, and that is, that they think owners of the gardens should plant the trees, and who shall prove that thought wrong? Whoever plants them the trees become part of the freehold, and indeed they increase its value as many a rent roll proves. I wish all rectors would use the influence which they possess in inducing landlords to make the homes of their humble neighbours homes indeed, by a distribution of fruit trees, as one of the neglected means of establishing a contented and home-loving peasantry. It may be that landlords imagine that the "sons of toil" do not care for fruit trees, but I can speak for my "old friends," and state that they do care for and prize them highly.

If the planting of fruit trees by owners could be brought about, I would not dispute for standards or pyramids; the trees in such gardens would soon settle that point. For the gardens of the clergy and those similarly circumstanced pyramid trees are highly appropriate, as being ornamental, instructive, and also profitable; but for filling with fruit old churns, clothes-baskets, &c., I like to see trees requiring a ladder once or twice a year. It is the preservation of such trees that I urge as important, trees which I fear have not always been estimated at their proper value. I have more to say on the subject of "old trees," but I must now be "off to work."—A RADICAL CONSERVATIVE.

In your paper of January 20th I read an article on old Apple trees. I think the writer of it has exaggerated the difficulties of dealing with them. I do not doubt that many Apple trees are too old to be cut or grafted, but my experience has taught me that a very large proportion of full-grown trees may be so dealt with.

Twenty years ago I purchased a farm with several acres of older orchards of old-fashioned sorts, full-grown trees, in a very crowded neglected state, and producing very little cider. I began (first thinning the tops of all), by cutting-off the whole heads of many trees and grafting them with better kinds. Of these a certain number died in some years, chiefly blowing down and had decayed roots. I then adopted the plan of grafting a part of a tree, say one-fourth to one-half of the higher branches, and in a few years gradually grafting the remainder. So far I have lost none of these trees, the grafts have all done well, and the wild shoots from the old stocks have been encouraged, except when their tops interfered with the grafts, till the trees had formed such large new heads that the wild shoots were unnecessary to help to furnish a top to give action to the roots. My consequent plan now is, to cut off a portion of a head and graft it each year for four or five years, as I may judge the age and condition of the old stock requires.

The general result has been, that at the end of twenty years my orchards are pretty full of old regrafted trees, which produce five or six times the quantity of cider that they did when I first began to regraft them.—A. Z.

MOAT BANK,

THE RESIDENCE OF ABRAM BASS, ESQ.

ALL connected with horticultural pursuits are justly proud of the patrimonial seats of the nobility and gentry, and the ability with which our "great gardens" are managed. Few of those places can be visited without their imparting instructive lessons to the observant visitor, and descriptions of them seldom fail to interest and add to the stores of knowledge of which members of the "ancient craft" are ever in search.

But besides the historical places of our noble families there are, scattered over the country in more or less of obscurity, those who are earnest workers in a small way, yet who bring to bear abilities worthy of recognition in the culture of some special flower or fruit. If we wish to see our national flower cultivated for "very love of its beauties" we must enter the precincts of some secluded parsonage, and there we see the Rose enthroned in regal dignity. It is so with many florists' flowers, and not unfrequently also with fruits.

How ably Grapes are grown by amateur skill was described on page 98, and now is noticed an unpretentious garden where not only Grapes but other fruits are cultivated to a degree of excellence that many gardens of greater fame might envy, or at any rate be proud to own.

Moat Bank is situated about two miles from Burton-on-Trent on the high ground overlooking the town and a great extent of country. It was once a Roman station, the moat still existing and filled with water, the "stronghold" which it encircles being now a plantation and orchard. About sixteen years ago Mr. Bass selected this commanding and healthy site for his residence, and erected thereon a Gothic structure from plans of the eminent architect Mr. Street of London. Gothic houses are frequently dark and not always convenient; but here it is not so, for a more light and cheerful, and also homely and convenient residence, it would be difficult to find.

From every room the view is splendid. From one standpoint the winding Trent may be seen in eight or nine places; from another Cannock Chase, Brethby, and the hills of Derbyshire are seen. Alton Towers, Tutbury Castle, Bar Beacon, twenty-five miles distant, are also within the line of vision, and the eye in sweeping the panorama can distinguish the spires and towers of not less than forty-eight churches. Such is the salubrious and commanding position of Moat Bank.

Now let us look at its gardens. In extent they are small, but in quality they are great. Surrounding the residence are Conifers in great profusion and, considering their age, of marvellous growth. The staple of the soil is clay; but that the shrubs and trees were not only well planned but were well planted by Mr. Barron is clearly manifest, and that they have been equally well tended by their owner their health and shape abundantly proves. The Cedars are numerous and exceedingly fine, also are Wellingtonias and Pinus laevis, grandis, &c.; and the Yews, Hollies, and other shrubs are of a size to render it a matter of surprise that the site they occupy was sixteen years ago a bare field. These Conifers are gratifying proof of what can be effected by solicitous care and well-directed skill. They are Mr. Bass's pride, and well may he be proud of them.

We next enter the walled garden, and find fruit trees of pyramids, bushes, and espaliers in superior health, their forms and fine fruit-bearing condition bespeaking them at once to be under a master's eye and hand. In order to have the outdoor fruits as perfect as possible Mr. Bass sent his gardener to take lessons from the Rev. C. C. Ellison of Bracebridge; and the result has been very gratifying, the gardener having proved himself an apt pupil of an able tutor.

We find also some glass structures. The small span-roofed plant house had Fuchsias trained up the rafters after the manner of Vines—a mode which shows the pendant blooms to the greatest advantage, and which is worthy of more general adoption. The Fuchsia rods are trained and pruned precisely similar to Vines. The plants in the house (Roses, Ferns, Camellias, &c.) were all looking well. But I cannot linger here, and pass to the vineries—small again—not the Grapes, but the houses. The Vines are in the first order of health, and produce splendid Grapes, fruit of a quality worthy of the table of a prince. These Vines reflect the greatest credit on the gardener, Mr. Deaville, who was trained at Trentham. The borders were made and the Vines planted under the personal superintendence of Mr. Pearson of Chilwell about eight years ago. The sorts comprise Black Hamburgh, Mrs. Pince's Black Muscat, Alicante, Muscat Hamburg, and Frankenthal; one Vine of Muscat of Alexandria having a small house to itself. At the time of my visit the fruit was out—the best having been distributed amongst friends, the remainder hanging in the fruit room. The crop was seen growing by Mr. Henderson of Coleorton and other well-known good judges, including Dr. Hogg, and was by them pronounced most superior. To the excellent border made by Mr. Pearson, and to the skill and vigilance of his gardener, Mr. Bass attributes the admirable state of his Vines.

I now arrive at the main object of my visit—the orchard house. I had heard of this house and seen some of its fruit—fruit which was pronounced of the highest excellence by the highest authority of the generation. This house and trees I thought worthy a visit—a visit to be remembered. Sir Tomman Moseley had kindly placed a conveyance at my disposal, deputed his gardener as coachman, but so bitterly wintry was the day—ice below and a drifting blinding snow filling the air, that we had "mercy on the beast," stabled the horse at Burton, and "faced the storm" on foot. It was a cold journey, but we had a warm welcome. Why? Because we were gardeners, and because Mr.—yes, and Mrs., Bass were, and are, gardeners too. Unfortunately Mr. Bass was confined to his room by illness, but he kept up a constant communication with his unseen guests by sending down first one fruit and then another,

with pleasant words that we should test their qualities—such Nonpareils and Calville Blanche Apples which only high orchard-house culture could produce.

The orchard house is a span-roofed structure 60 feet in length by 20 feet in width. It contains a principal central border, also side borders. The principal border is occupied by standard Peach and Nectarine trees planted out; and arranged beneath them are dwarf trees in pots. The side borders are occupied by trees in pots of Plums, Cherries, Apples, &c. The principal Peach trees are large-sized, symmetrical trees, each producing five to eight dozen of fruit. They have been skilfully managed, and literally bristle to their centres with fruit-bearing spurs. The sorts are Grosse Mignonne, Royal George, Noblesse, and Bellegarde Peaches, and Pitmaston Orange and Lord Napier Nectarines—an admirable selection, and probably not to be equalled by any other half-a-dozen sorts. The fruit from these trees is of the highest excellence. Black Hamburg and Royal Muscadine Grapes are grown in this house, and Mr. Bass considers that they are quite as good or better in flavour than those grown with more pretence and expense.

The Apples in pots comprise Margil, Calville Blanche, Cox's Orange Pippin, Ribston Pippin, and Nonpareil. Respecting the fruit from these trees it is not too much to say that those who have not tasted it, or other fruit similarly grown, have yet to learn the full value of these sterling sorts. Both in appearance and flavour Apples from well-grown orchard house trees far surpass the best specimens under even favourable garden culture. All the trees in this house are in the first condition of health and fruitfulness, and they are in the sole charge of Mr. and Mrs. Bass, who train, prune, pinch, and water them. The orchard house is their recreation ground—their "hobby;" their pleasure is to grow and give—a delightful, wholesome, healthy life. Mrs. Bass is a pomologist who can hold refreshing converse on the subject which she practises so successfully. The modes of pruning and pinching of the fruit of English and continental growers are familiar to her "as a tale of love." Her work is indeed a work of love—love guided by skill and crowned with success. It is refreshing to notice how much pleasure a garden can give and what benefits it can confer; and especially is it pleasant to feel that these pleasures and benefits are at the call of all who own a garden, however small it may be, if they only put "their heart in the work" of tending it.

My visit to Moat Bank was on one of the coldest of days of my garden "exploring" experience, but I was rewarded with the "discovery" of one of the warmest welcomes I ever met, and a garden which by the soundness of its management is worthy of a warm tribute of recognition.—J. W.

THE FLOWERING OF SPRING PLANTS.*

THE observations which have been made by Mr. McNab on the flowering of spring plants in the open air in the Edinburgh Royal Botanic Garden during the past twenty-six years, have been published in the Transactions of the Botanical Society of Edinburgh. These observations have been made by the same observer on the same plants growing in the same situations during the whole of the twenty-six years.

The average day of flowering of thirty-two spring flowers has been determined, of which the following are examples:—*Galanthus nivalis*, Jan. 25; *Eranthis hyemalis*, Jan. 30; *Hepatica triloba*, Jan. 31; *Corylus Avellana*, Feb. 2; *Rhododendron atrovirens*, Feb. 8; *Crocus susianus*, Feb. 4; *Leucojum vernum*, Feb. 10; *Daphne Mezereum*, Feb. 22; *Narcissus pumilus*, March 10; *Orobis vernus*, March 11; *Muscari botryoides*, March 18; *Ribes sanguineum*, March 22; *Narcissus pseudo-Narcissus*, March 31; and *Fritillaria imperialis*, April 1.

The lateness or earliness of the different springs, as determined from the times of flowering of the thirty-two plants in each year, is considerable. The latest spring was 1855, which was thirty days later than the average, and the earliest 1874, which was twenty-three days earlier, thus giving a difference of fifty-three days between the latest and earliest springs during the past twenty-six years. As regards particular flowers the deviations are much greater; the largest deviations from the average dates of flowering occur before the time of the

equinox, when deviations of from five to seven weeks either way are of repeated occurrence; but after the equinox the deviations are markedly less, seldom reaching three weeks.

The springs of 1855, 1856, 1857, 1865, and 1870 were late throughout; and on the other hand, the springs of 1851, 1862, 1863, 1868, 1869, 1872, and 1874 were early throughout. Great variations have occurred in other springs, such as 1864, which, being preceded by a very mild December, many spring plants came into flower in the end of 1863. But in January the temperature was 2°·0 under the average, and in February 5°·2, and vegetation was consequently arrested. March was also under the average, and the weather did not improve till April 3, the mean temperature of this month being 1°·7 above the average. The disturbing influence of this abnormal weather on the dates of flowering was in some cases very great. Thus, *Sisyrinchium grandiflorum* flowers on the average eleven days earlier than *Daphne Mezereum*, but in 1864 *Daphne Mezereum* did not come into flower till eighty-six days after *Sisyrinchium grandiflorum* had flowered. It is the occurrence of these disturbances which render a long series of years necessary in order to arrive at a sufficiently close approximation to the true mean dates of flowering.

As regards Edinburgh, January 11 may be considered as the turning point in the winter temperature, since previous to this date the temperature is, on the whole, falling, and after this date it continues steadily to rise. Further, after this date the rainfall becomes less, clear weather is of more frequent occurrence, and the increase in the temperature is very largely due to an increase of sunshine. The extremely slow rate at which, up to the end of February, the mean temperature rises, and the small differences among the temperatures up to this date, and the large number of plants—fourteen in all out of thirty-two—which come successively into flower during the interval, suggests that it is not so much absolute temperature that calls for consideration as the accumulated amounts of the preceding daily temperatures, in the extent to which these rise above freezing. The accumulated temperatures, thus calculated, are—for *Galanthus nivalis*, 72°·7, and *G. plicatus*, 146°·4; for *Crocus susianus*, 125°·2, and *C. vernus*, 179°·1; for *Rhododendron atrovirens*, 120°·3, and *R. Nobleanum*, 249°·3; and for *Narcissus pumilus*, 347°·0, and *N. pseudo-Narcissus*, 540°·1. Similar data prepared for other places, in this and other countries, would be very instructive in showing how far the order of dates of flowering in Edinburgh is observed in other places, and what is the relation of the dates of flowering at each place to the accumulated temperatures at that place, and what modifications are brought about by purely climatic differences, particularly as these occasion different results as respects the heating and actinic rays of the sun.

The thirty-two plants, whose dates of flowering have been determined, include three varieties of one species—viz., the blue, white, and red varieties of *Scilla bifolia*. Of these three varieties the blue flowers first—viz., on March 7; next comes the white variety, on March 17; and lastly, the red variety, on March 21; the red being thus a fortnight later than the blue variety.

An interesting question may in this connection be raised with reference to the relation which the colours of flowers have to the dates of flowering. With this view, our British wild plants have been grouped according to the different colours of their flowers and the months in which the flowers usually first expand, the data being taken from Dr. Hooker's "Students' Flora of the British Islands." In classifying the plants, red includes pink, crimson and scarlet; and green, all greenish-white, yellowish-green, and greenish-purple flowers. Grasses, Carices, and other groups, characterised by inconspicuous floral envelopes, are excluded. The list examined includes 909 species, of which there are 257 with white flowers, 238 with yellow flowers, these two being nearly a half of the whole number; then follow red, 144; purple, 94; blue, 87; green, 51; and miscellaneous, 88. Taking each colour by itself, and calculating the per-centages of that colour which has come into flower by each month from April to July, we obtain the following results for the first five classes:—

	April.	May.	June.	July.		April.	May.	June.	July.
Blue	18	48	71	98	Yellow	9	24	61	98
White	14	38	70	97	Red	9	25	63	94
Purple	4	28	61	92					

Thus of these colours, the blues are, on the average, considerably the earliest in flowering; then follow in order the whites and the purples, and lastly, the yellows and reds. It follows that the plants included in the British flora clearly

* Abstract of a paper read before the Edinburgh Botanical Society on the 18th ult. The paper itself is in type for the Journal of the Scottish Meteorological Society.

tend to arrange themselves, as regards the dates of flowering, in the order of the colours of the spectrum, the average earliest being those which are nearest the part of the spectrum where the actinic rays are at the maximum. It will be observed that the differently-coloured varieties of *Scilla bifolia* are in the same order of flowering of the plants of the same colours in the British flora.—ALEXANDER BUCHAN.—(Nature.)

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

Our first sowing of *Peas* are through the ground, and only require mild weather to progress favourably. We have made another sowing, and this time Fillbasket and G. F. Wilson have been put in with the early sorts. These will come in when Alpha, Dr. Hogg, &c., are over. It is a good plan to sow *Peas*, and also *Beans*, thickly in shallow boxes, where they can be started in a little heat, and gradually inured to the cold before planting them out. The young plants must be carefully transferred from the boxes to the open ground, for if they are planted in a careless manner, or without being inured to the cold, they will not do so well as those sown in the open ground. In sowing the *Peas* out of doors at this early season a deep drill is drawn, which is only partially filled up, a ridge of soil being left on each side. These slight ridges about 8 inches high shelter the young *Pea* plants from cutting frosty winds; and as the plants advance in growth the sides are filled in, which is preferable to earthing the rows up, especially in dry soils. In very wet districts this might not be an advantage.

The middle of the month will be a good time to plant out early *Potatoes*. A common practice is to plant with a dibber over the ground has been manured and dug. Others draw drills about 6 inches deep with a hoe, in which to plant. Our practice is to plant as the ground is dug, using a line to cut out the space for the tubers. This is quite as expeditious as any of the other methods, and treading upon the ground afterwards is avoided.

When the weather is favourable the hoe is kept at work amongst growing crops; we are also digging-in the manure that had been spread on the fruit-tree borders. The early *Cabbages* must be earthed-up. The *Cauliflower* plants in boxes have been placed in a sheltered position out of doors. They will be planted out if the weather continues favourable. Some seeds of Early London and Walcheren have been sown in a hot-bed to succeed the autumn sown plants. We do not allow the young plants to remain longer in the heat than to develop the seed leaves. The boxes are then placed in a cool frame, and the plants are pricked out in a few days after hardening. Lettuce, Radishes, Mustard and Cress, and Chervil, for use in the kitchen, and other salad crops, are now sown out of doors. Roots of Mint and Tarragon must also be lifted, and a few pots of them placed in heat.

PINE HOUSES.

There is nothing being done in these houses different from what has been stated in a previous number. As the days lengthen a slightly higher temperature has been kept up with more moisture in the house, and water in the evaporating troughs. The days have been sunny, which allowed of 70° at night when the nights were not cold; if dull weather, with frost outside, should set in, 65° is quite high enough in any of the houses. We have out ripe fruit this week, and others are in various stages of ripeness, and there are plenty of plants that will throw up fruit during the next six weeks, so that a succession is ensured. Soil has been prepared for succession plants and suckers. Our light sandy soil is not well adapted for *Pine*-growing, and it is necessary to obtain clayey loam from a distance; but the dealers will not cut the surface spit so shallow as we do. They seem to dig it out, and very little turfy material is obtained in a cartload. By mixing this top spit with our own turf cut thin from grass land, a good compost is obtained. We mix as follows: Five barrowloads of loam to one of rotted manure, and to every barrowload of the compost is added an 8-inch pot of crushed bones, and as much charcoal broken into pieces as large as pigeon's eggs. This compost is best mixed two or three months before using it, and should be used in a moderately dry state. A wooden rammer is used to make the compost pretty firm in potting.

PLANT STOVE AND ORCHID HOUSES.

Many plants in the stove are now starting into active growth. We are potting those hardwooded plants that require it. Specimen plants are carefully looked over for mealy bug, for if this pest should gain a lodgment on such plants as *Ixoras* or *Stephanotis* it will sadly disfigure the flower trusses. The young growing wood of *Dipladenias* must be trained to fine string run up and across the rafters, one end of the string being fastened to the trellis to which the plant has been trained. The growths are trained near the glass until the flowers are formed, when

the strings are cut and the young growths carefully trained round the trellis. *Stephanotis floribunda* is also grown in this way, except that the young growths are made the previous season, and well ripened by exposure to the sun. The large specimen plants shown at the metropolitan exhibitions are managed in this way. The plants would not be nearly so well furnished with flowers if the growths were tied down to the trellis as they are made.

Palms that are in small pots for the size of the plants will be potted at once; larger plants that are not suffering will be potted later, say about the middle or towards the end of April. Ferns should not be allowed to become pot-bound if it is intended to make fine specimens of them. Plants that have received a check seldom make handsome specimens. *Adiantums* should be placed in the sunniest part of the house, and they like more turfy loam in the compost than some of the others. The Australian tree Ferns, although they may be wintered in the greenhouse, and will produce new fronds there during the summer months, succeed better if they are now removed to a house with a night temperature of 55°, and where they can be well supplied with atmospheric moisture. They should also be repotted before the young fronds are thrown-up.

We shall also repot many of the *Orchids* as time permits; a large proportion of them are best shifted at the time they start into growth. It is of the greatest importance to drain the pots well, using clean crocks; the pots used should also be quite clean. A very large proportion of *Dendrobiums* do best in baskets where they can be hung up close to the glass roof. If wooden baskets are used, the best material to make them of is teak; but those made of potteryware, and recently advertised in these columns, are durable, and equally well adapted for the plants. If it is thought better not to repot or rebasket some of the plants, a little fresh sphagnum and fibrous peat should be placed on the surface of the pots or worked into the sides.

FLOWER GARDEN.

We have pruned a portion of the *Roses*, the others will be left until the end of the month, or later, to insure a succession of bloom. A month hence will be time enough to dig-in the surface-dressing; this we generally do for the sake of neatness. If it is necessary to water when the hot weather sets in, a fresh dressing of rotted manure may be applied. A mistake is often made in pruning, and that is to leave too much young wood and not to cut it back enough. The shoots in the centre of the tree should be well thinned-out, all the very weakly and gross growths to be removed, leaving only those of moderate growth. The knife should not be used at random, but the shoots should be cut at an outside eye; if the cut is made at an inside eye the growth will be thrown into the centre of the tree, and still further tend to crowd it. Budded *Roses* that have made only one season's growth should be cut back to three or four eyes. Weakly growing Hybrid *Perpetuals* should be cut to 2 or 3 inches, while those of the most robust growth may have a foot or more of the young wood left.

Phloxes are now pushing strongly in the open ground. The cuttings have been put in—one in the centre of a small pot. They may be potted three or four in a 60 sized pot, and repotted singly into 60's after the cuttings are rooted; but the other system saves trouble, and as the pots are placed in a gentle hot-bed the cuttings very soon strike root; not 5 per cent. fail.

Beds of *Pinks* have been stirred up a little on the surface, and the plants made firm in the beds by pressing around the roots with the fingers. *Carnations* and *Piotees* in pots in cold frames ought to be looked over and have any decayed leaves removed, and the surface of the soil just stirred up with a label. We have not yet had time to do ours, but the plants are exceedingly healthy.

Auriculas have all been looked over. A few have been repotted, and the remainder surface-dressed; a little of the old mould is removed, and some material composed of about equal parts loam and cow manure put on to replace it. All superfluous offsets are removed at this time and placed in small pots. Any plants of a scarce sort, especially if the plants are tall, should be headed-over a little above the surface of the ground. The top will strike out roots readily in a short time if it is covered with a bell-glass and not overwatered. The bell-glass should be removed occasionally and wiped with a dry cloth.

We were able to obtain late in 1874 a very small plant of Taylor's Glory, one of the scarce varieties. It gave no increase up till April last year, when it was not much larger than it was when purchased. Risking all on one venture the top was cut off, and made a nice plant the same season. Offsets soon formed from the old stool, and from that one little plant of Glory nine plants have been raised; some of them are still very small, but they have lived through the winter, and are all starting into growth. We cannot always expect a hit like this, but if a plant of any scarce sort refuses to throw offsets with us, its head is struck off. Mrs. Sturrock and Meteor Flag gave one offset each only, but that is two plants instead of one. With care there is not much fear of losing the top. The weather is

severe, and the lights have been kept over the plants, admitting a little air at the back.

We also continue to pot-off Zonal Pelargoniums, and to place Verbenas, Ageratums, &c., in shallow boxes. Cuttings of Verbenas, and any other plants of which the stock is not sufficient, are put into heat. Early spring-struck cuttings of such plants are better for bedding-out than the old plants.—J. DOUGLAS.

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

LEEDS (Spring Show). March 15th and 16th. Mr. G. Forbes, 108, Hyde Park Road, Sec.

BRIGHTON (Spring Show). March 22nd and 23rd. Mr. G. Wobley, Holm Wood, Westbury-upon-Trym, Hon. Sec.

ROYAL CALLEDONIAN HORTICULTURAL SOCIETY. Shows April 5th, July 5th, and September 18th.

WESTMINSTER AQUARIUM. April 18th and 19th, May 10th and 11th, [May 20th and 21st, July 5th and 6th, October 4th and 5th.

TYNARTON. May 24th and 25th. Messrs. A. Payne and J. Mills, Hon. Secs.

SOUTHAMPTON. June 5th, and August the 5th and 7th. Mr. C. S. Fridge, 89, York Street, Sec.

MAIDSTONE (Roses). June 21st. Mr. Hubert Bensted, Rocketow, Maidstone, Sec.

SPALDING. June 21st. Mr. G. Kingston, Sec.

RICHMOND. June 29th. Mr. A. Chancellor, Hon. Sec.

SOUTHPORT. July 6th, 7th, and 8th. Mr. E. Martin, Sec.

HELENSBURGH (Roses). July 12th and 13th. Mr. J. Mitchell, Sec.

BRIGHOUSE. July 29th. Messrs. C. Jessop & E. Rawnsley, Hon. Secs.

PRESTON. August 16th and 17th. Mr. W. Troughton, Hon. Sec.

SEATON BURN. August 26th. Mr. R. Richardson and Mr. W. Elliott, Secs.

DUNDEE (International). September 7th, 8th, and 9th. Mr. W. R. McKelvie, 95, Euclid Crescent, Sec.

TRADE CATALOGUES RECEIVED.

Stephen Brown, Weston-super-Mare.—*Illustrated Seed Catalogue and List of Bulbs for Spring Planting.*

Kelway & Son, Langport, Somersetshire.—*Spring Seed Catalogue and Amateurs' Guide.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

NEW CLIMBING MELON (H. B. B.).—We do not know to which Melon you refer. You must be more explicit.

ROYAL HORTICULTURAL SOCIETY (J. T.).—The address, "Secretary, Royal Horticultural Society, South Kensington," is sufficient.

SHOWING ROSES (R. C.).—The Roses are best shown with leaves, but they must be leaves attached naturally to the sprays bearing the flowers. Leaves not belonging to the Rose exhibited are inadmissible.

HEATING A VINERY (L. D. E.).—To maintain the temperature "of 80° under all weathers" you will require 580 feet in the case of the thermometer being at zero, which is one of the many extremes that may be drawn from "all weathers." Every requirement of the Vines, however, will be met in your case by six rows of 4-inch piping the length of the house, including returns and a flow and return across one end, or about 120 feet including syphons.

INACHING VINES (Richard Walker).—The best time to do this is soon after growth is made, there being a few leaves on both stock and scion to appropriate the sap, and thereby lessen the liability of bleeding. The speediest union is effected when the growths of the current year are operated on, both stock and scion being soft and unripe. The earlier it is done the greater is the certainty of securing a good growth and its thorough ripening.

FLOWERING STOVE PLANTS (G. B. U.).—In addition to Stephanotes, Eucharis, Ixora, Fraxinosa, and Gardenias, the following are of easy culture:—Aphelandra aurantiaca Rozeii, Bougainvillea glabra, Burchellia capensis, Centropogon Lucena, Conoclinium lanthornum, Dalechampia Rozeiana rosea, Eranthemum pulchellum, Euphorbia jaquiniflora, Poinsettia pulcherrima major, Rondeletia speciosa major, Scutellaria Mocciniana, and Thysanacanthus rutifolius. We add a few bulbous plants—Pancratium fragrans, Hippeastrum peruvianum, Imantophyllum minutum, Gesnera exoniensis, Griffinia hystrix, and Ureolonia aurea. Anthurium Scherzerianum you must have if you have it not already, it being one of the very finest stove flowering plants.

CUPRESSUS LAWSONIANA BREVEA VIRIDIS (Villa Garden).—It is one of the most beautiful of Conifers for a small lawn, and you may plant it with confidence. It is hardy, of free growth, dense and conical in habit, and almost as green as a Laurel.

RABBITS AND TREES (A. Dumbell).—The rabbits must be destroyed, or excluded by 2 feet 6 inches wire netting, which we employ until the trees are considerably advanced, and even then many succumb to rabbits and hares.

It is remarkable the eagerness that rabbits exhibit in attacking recently introduced plants; even the kinds they usually do not attack they will nibble at for a considerable time after planting, whilst others of the same kind grown on the spot they will not interfere with. Plenty of food is no safeguard, we being surrounded by park land and rough young plantations, which give us no freedom from their ravages. We might have helped you to a selection of some shrubs which these animals do not greatly injure; but you appear to have planted.

DESTROYING MICE (Edward Fisher).—Arsenic will destroy the seed, and is besides dangerous to use. We moisten, in fact make wet, every kind of seed before sowing, and coat them with red lead, and neither birds nor mice interfere with them; rats even not caring to molest seeds well coated with the red lead. Set a number of figure-4 traps baited with cheese "crust," and keep a cat—not to be made a doll of. A good one is invaluable as a sear of birds and for mousing; ours being famous at catching crickets.

CINERARIAS "BLIND" (E. M. P.).—The state of the plants is a consequence of defective roof-action, or a result of deficient light and temperature. If the latter they will improve as the season advances. See reply to "J. S."

TRANSPLANTING FRUIT TREES (M. D.).—You may safely remove the trees now, carefully preventing their roots being dried in the course of removal, and the trees will grow as well as if they had been planted in November. Trees planted after the middle of November seldom make fresh roots until the spring. We have planted fruit trees with great success even when their buds were swelling; but the roots were not exposed to the air more than a few minutes.

CINERARIAS NOT FLOWERING (J. S.).—If your plants are healthy, and especially if their roots are in an active state, they will flower freely as the season advances. It is common at this period for the petals to be slow in their movements, and as a consequence plants have occasionally been hastily condemned. With patience and good culture, not allowing even a trace of insects, watering the plants regularly, and occasionally with weak liquid manure, they will eventually expend their flowers freely.

GARDENERS' APPRENTICESHIP (A.).—We think no advantage would result from binding the boy to his father. Let the parent give his son good instruction for a year or two, and then seek to place him in some other good garden, when his own skill and perseverance would meet with the reward of promotion.

PLANTS FOR CUT FLOWERS IN JUNE (A Subscriber).—White or light pink will only be admissible for wedding bouquets. A few that may be had in flower at that time are:—*Stove plants*: Cierodendron Balfourii, Gardenia radicans major, Ixora acuminata, Pentas kermesina, Stephanotis floribunda, and Eucharis amabilis. *Greenhouse plants*: Abutilon Boule de Neige, Apocynon distachyon (an aquatic), Orange, by retarding in a cool house, Dracophyllum gracile, Jasminum grandiflorum, Mandevilla suaveolens, Myrtles, Rhynchospermum jasmynoides, Azalea indica, var. Borsig, Comtesse de Ribemourt, Narcissiflora, Raphael, Criterion, and Milla. *Marie Lefebvre Pelargoniums*.—*Show*: Claribel, Countess, and Coronet. *French and English Spotted*: Emperor of Pelargoniums, Madame Mignon, and Fortunio. *Fancy*: Fanny Gair, Lady Dorothy Nevill, and Princess Teak. *Zonal Pelargoniums*: Delight and White Clipper. *Double*: Alice Crouse and Madame Lamola. *Ericas*: Exquisite, infata alba, jasmyniflora alba, ventricosa var. Bothwelliana, albo-tincta, hirsuta alba, and vesita alba. *Rhododendrons*: fragrans jasmyniflora, and Princess Alice. *Pimeles decussata*, P. Hendersonii alba, and P. spectabilis rosea. Hardy plants will be represented by Roses from walls, Mock Orange, Deutsia crenata flore-pleno, Lilac, Narcissus, Pinks, Spiraea japonica, and many others.

CLIMBERS FOR COLD FRAMERY (J. Brown).—From the moisture and the shade that will be necessary for the Ferns we do not consider flowering climbers suitable, and we should cover the pillars with green and variegated Ivies, and Ficus repens. We name the following climbers for the roof:—Begonia capricornata, Caprifolium luteum, Lardizabala bitemata, Jasminum revolutum, Bridelia spicata, Berberidopsis corallina, Ceanothus aureus grandiflorus, Crataegus pyracantha, Passiflora caerulea, Caprifolium brachypodium aureum reticulatum, Solanum jasmynoides, Lapergeria rosea would probably succeed, but we do not recommend any of them. Deciduous plants may be Clematises Albert Victor, Jackmanni, Henryi, and Glycine sinensis. Except the varieties of Ivy, especially the small-leaved, and Ficus repens, we think them inappropriate. Why not cover the pillars with Lygodium scandens, and shade the roof in summer?

SOWING HOLLY BERRIES (T. F.).—Sow them now or in March on the east border in the kitchen garden, but you might if the ground be valuable keep the berries for a year in a heap in the ground, and not sow them until this time twelve months. The seeds will not, if you sow now, germinate until the second year.

DAFFODILS NOT FLOWERING (R. S.).—The growth is probably too free. Restrict the pot room, and expose the plants fully to light after the growth is made. With the Lapergeria we think the case is different, it requiring more pot room and more liberal supplies of water. You, however, give us no particulars, and we cannot in the absence of those give definite advice. Our "Greenhouse Manual" would help you to their treatment, post free from our office for 10d. "Fairy rings" may be destroyed by making holes where they appear with a crowbar, and saturating the ground with lime-water, made at the rate of 19 lbs. of quicklime to thirty gallons of water. It will be clear in forty-eight hours, and should then be applied.

SILICATE MANURE (H. M. Y.).—We cannot give you the information you need; but we can say that we never knew an instance in which it prevented the Potato disease.

LOW TEMPERATURES AT NIGHT (J. S.).—The remark does not call for any severe comment.

KILN DUST (J. S.).—Kiln dust is an excellent manure, much superior to spent hops for either Onions, Peas, or Potatoes. We have used it with great success with these and other crops.

NAMES OF FRUITS (J. D.).—C. Braddick's Nonpareil; 6, Scarlet Nonpareil; H, not known; 111, Cockle's Pippin; 1, not known; F, Thompson's. (Continued Subscriber).—1, probably Cobham; 2, Sturmer Pippin; 3, Golden Harvey. (L. Garnett).—The large Pear is Huxley's Prince of Wales. No. 1, very like Beurré d'Arenberg. We do not know what else it can be. 2, Passe Colmar. This requires a warmer climate than yours to ripen it properly. Can you give us any account of the Greenwood Russet?

NAMES OF PLANTS (G. G.).—Justicia coccinea, Scarlet Justicia. (R. S.).—We cannot identify plants from their leaves only; we must see the flowers also.

POULTRY, BEE, AND PIGEON CHRONICLE.

OUR BREEDING PENS.

UNDOUBTEDLY February is a very important month to all poultry fanciers. In this month we have most of our choicest birds penned-up for breeding. We collect with pleasure every egg laid, and we set them and look for the broods from them as our strength for another year. Most certainly, then, this is a month of great importance to us all, and yet it is a time that is not sufficiently valued by many.

Some fanciers think that so long as they obtain the eggs and are able to sit them, in these times of scarcity of broody hens, all must be well; but it is not so, for very much depends, more than is generally supposed to be the case, upon the strength and condition of the breeding pens when the eggs are formed and laid.

We can all remember, many of us sorrowfully, the dire failure of the early 1875 chickentide; and although we are, of course, much at the mercy of the weather, still a few hints on the management of our breeding pens at this time will be, perhaps, acceptable.

It is all very well to collect the eggs regularly and keep them from the frost, to place them under good hens, and to keep them damp and sprinkled with water; but none of these remedies are of much use unless the hens which laid the eggs and the cocks with them in such breeding pens are active and in good condition.

We believe there is nothing so fatal to the chances of large and strong chickens as to continually show the stock birds. They cannot endure it, and in the heavier breeds more particularly, such as Dorkings, Cochins, and Brahmas, the less often the breeding birds, especially the cocks, are shown the better.

We have asked many of our great breeders, and we learn from nearly all that they have different birds for breeding from and exhibiting, and hence they obtain their early chickens so strong and fine. Mr. Sedgwick, we think, would not have his early Cochins so large and forward if he was to be exhibiting his stock birds all the winter. Of course this gentleman, to a great extent, makes the summer shows his *specialité*. Still, many can and do make all-the-year-round exhibiting, and breeding as well, work successfully. This requires, however, a large stock of birds and a large space.

It is, moreover, at the bottom of much disappointment in the egg-vending line, for the eggs laid by hens in a pen where the male bird is being, or has been, overshadowed, are consequently often clear. Consequently, in justice to an egg-buying public, the birds in the yards which are looked for to supply sittings of eggs for incubation should be strong and not weakened by over-work, however good they may have been or are for the exhibition pen.

Shows have for the next few weeks, to a great extent, ceased; still there are some about, and it is never too late to be forearmed, for we have known birds taken from a run for one show only made useless for two or three weeks' breeding.

Then as to the feeding. At this time birds need to be very plentifully supplied with good food. Because they are not destined for the show pen for the present their usual fare should not be lessened, it should rather be increased, for there is much more expected of the birds, and we must try to sustain them by good and generous diet. We think the hens also need extra food now, and that good. As a rule, we are no advocates for allowing birds to have pans of food ready to go to at pleasure in their pens, but we do not object to it at this time of year, so have pans of soft food generally in our runs. The birds, especially the cocks, seem mostly hungry, more so than at other times. Thus it would seem Nature points out that the male birds do require plenty of nourishment at this time, for it is quite unusual for cocks, as they now do, to leave their harems and feed quietly by themselves without even using those insinuating powers they would seem to have of calling their ladies to them.

We have had this point called to our attention by four or five friends within the past two or three weeks: and so it would seem that many have seen its importance, and are acting upon it. The breeding pens at this time should be well housed. They do not need artificially heated roosting places, but the birds want to be in a sound building, well walled and warm, and yet properly ventilated. Birds kept in exposed places and where the houses are open to winds, and cold, and damp, ought neither be expected to lay well nor to produce good chickens.

There is plenty of time to make the desirable arrangements if commenced without delay, and the more care and attention we pay to the stock birds in this and the next two months so much larger a percentage of fertile eggs and strong chickens shall we have as our reward.—W.

GAME BANTAMS.

No fowls will afford more pleasure to the keeper than these little pets. The clear merry crow of the cock, his proud strut and readiness to defend himself against all attacks are a continual source of amusement; while the nimble little hen ever on the look-out and guarding her brood with the most unrelenting care, cannot but be admired by anyone who will watch the graceful movement of her stylish little form. Of the many varieties kept at different times, none have given more pleasure and satisfaction. On account of their diminutive size, many at once class them as a delicate variety. This is, however, an error, which a little time given to the rearing of them will soon dispel. From quite a limited number of old birds I have this season raised a large flock of very promising chicks, and my experience is that they are quite as hardy and require as little attention as most other varieties. They mature rapidly, and being good foragers the young soon say good-bye to the old hen and look out for themselves.

Game Bantams may be divided into four principal classes—Black-breasted, Brown-breasted, Duckwings, and Piles. White, Black and Wheaten are also reared, but the first four are chiefly bred and much superior to the others in all respects. My ground being limited, I have confined myself to but two of the varieties, Black-breasted Reds and Yellow Duckwings. As the great points to be attained in these varieties are style, hardness of feather, clearness and beauty of plumage, these properties should be carefully sought after in selecting your breeding pens. The cock should be neatly built, hard in feather, handsomely marked, and as small as possible. When speaking of size, I mean as he appears to the eye, not weight. A close hard-feathered bird often the very picture of symmetry and neatness, will sometimes weigh, by several ounces, more than another loose-feathered and apparently larger and less desirable one. A cock, however, if he be in good healthy condition, and is small to the eye, light in weight and of stylish build, is certainly a desirable bird. He should have a long head, slim, graceful neck, well-developed breast, finely tapered body, wings well tucked up, tail tightly closed and only slightly elevated, legs rather long, slender, and willow in colour. The hen should be small and gracefully built, long slim neck, compact body, wings well carried off, narrow tail, legs rather long, and matching in colour with the legs of the cock. The plumage should be bright, evenly pencilled, and as free from uneven spots on the wings as possible. The birds should be mated and placed in the pen early in March, but I would not advise setting any eggs before the beginning of April in this latitude. Early in the season nine eggs are plenty to give the hen, and later eleven or twelve.

Game Bantam hens make excellent mothers, but, when they cannot be spared, a lightly built Game hen is the best substitute. Moistened earth with a light covering of well-broken straw makes the best and is the most natural nest, while a good dredging of flowers of sulphur over the nest before setting the hen will keep it free from lice. In ordinary weather and with an attentive hen the chicks may be looked for on the nineteenth day, and if the hen is quiet leave the chicks with her until all are hatched. Nothing will strengthen the young brood and give them so good a start as the natural warmth of the mother. If the eggs are given to the hen so that the nineteenth day will end with the evening, the great majority of the brood will be found to come out during the night when all is quiet, and in most cases will be found to work well. Pen the hen on a dry piece of ground, in front of a good sod if possible, and where the morning sun will strike the coop. For the first few days give the chicks a mixture of hard-boiled eggs and fine bread crumbs well mixed. Feed them after, five or six times a day, but no more at a time than they will quickly pick up with a relish. After the first week a mixture of ground oats and middlings made with water into a crumbling mass will be found to be a good, substantial, and safe food for them. This food should be varied, however, by giving them every day some good sound wheat, and occasionally a very little cracked corn may be added.

Nothing are they more fond of than cooked meat chopped fine; but while a little will help to keep them in good heart, too much only tends to force them into that overgrowth which with Bantams is particularly to be avoided. When the chicks have free access to a good sod, and a patch of good earth to scratch in, all such articles as old mortar, cracked bone, ground oyster shells, &c., are not required. When, however, the ground is limited they may be used to advantage, and a little finely ground bone mixed with the soft food will greatly tend to strengthen the fast-growing chick.

When the chicks are five or six months old they and the old birds should be fed principally upon good sound wheat, now and then a little cracked corn, and in cold weather have the morning's meal of warm soft food. The scraps from the table are always in demand, but see when given that none is left after the meal to be trampled upon and become sour. The house for these little birds should have a warm exposure, and so built

that, while there is plenty of means for ventilation, it may in cold damp weather be so closed as to avoid any draught. A well-covered shed next to the house, if it can be built, will be found of great advantage in winter. With a pile of well-sifted dry ashes under it they will often be found there dusting and sunning themselves when the snow-covered ground has greatly contracted their available room.—CHAS. E. LONG.—(*American Fanciers' Journal*.)

[The above is a pleasantly written article, and will be useful to our American friends. The state in which the Game Bantam fancy among us is, as it appears to me, as follows:—When they were new birds they pleased everyone except the steadfast fanciers of the old varieties. The entries at our shows were extremely large. This went on for some time; but, as in all fancies, a turn came. Thus at the last Bristol Show, the third largest in the kingdom, there were more Black Bantams shown than there were Game Bantams (Black-breasted and other Reds), and the Sebrights were nearly as numerous as the Game Bantams of any other variety. The class for Game Bantam cocks again was not very large. The winners in all the Game Bantam classes were good, but the classes generally not so good as formerly.

It comes I think to this, that now Game Bantams have found their proper level and their right place. They are a beautiful variety, but at one time they threatened to extinguish all the other varieties. Sebrights have advanced. So have the Blacks, and I much wish that more Whites were shown, though they are looking up without doubt.

Next for a special word about Game Bantam cocks. A time will come when I hope all dubbing will be at an end. I am glad to see that a case has recently been brought before the magistrates in regard to the dubbing of the larger breed. Game Bantams being frequently ladies' pets, I think they might be shown "dubbed or not dubbed." This would be the thin end of the wedge, and it could be driven home by improved public opinion presently. Once let all Game cocks be dubbed and cockfighting is for ever done away with. Its kindred sports (sports indeed!), bull-baiting and badger-drawing, are no more, and the duellist and prizefighter are equally blackguards in the eyes of society, and both can be arrested and punished. We are now heartily ashamed of the cruelty of our forefathers, and may every trace of it be washed out, and one trace is dubbing.—WILTSHIRE RECTORY.]

PROFITABLE POULTRY-KEEPING.

In your last week's Journal, under the heading "Unprofitable Poultry-Keeping (?) " a correspondent gave a statement of the number of eggs he had in the year from his fowls, and what they cost in food, &c. He stated his profit on the year to be £5 odd, and he considered the result unsatisfactory. I am able to give what I hold to be profitable fowl-keeping.

Your correspondent began the year with twelve hens and two cocks. I commenced on February 1st, 1876, with nine hens (two were young pullets) and one cock—cross-breeds, some good some bad. On March 30th I had one more hen—a very poor Black Hamburgh. Enclosed I hand you the results obtained. My stock now for the most part consists of good birds—a mixture of Brahmas, Cochins, and Dorkings, having exchanged or bought in two good Brahma cocks. Having sold many of the eggs and consumed the remainder, killed some of the fowls and pullets for home use, and reckoned all at average market prices and carefully taken stock, I find the profit for the year to be as nearly £7 as possible. My gardener who is a lover of all live stock has had the entire management of my poultry. He feeds early in the morning with warm stimulating food, and thrice daily with Indian corn. The accounts I have carefully kept myself:—

—W. W. WEBB, Longlands, Stourbridge.

READING PIGEON AND CAGE BIRD SHOW.

We expressed a hope last year that an annual treat might be in store for us in the Reading Pigeon and Cage Bird Show. It has come round again with February 1876. The Pigeon Show was decidedly a better one than last year, many classes having been added, and that of cage birds was at least as good, which is much to say. The arrangements were as before excellent, and the temperature charming (we fear the birds on their homeward journeys will not say the same of the external atmosphere), and so exactly were many of the specimens in the same

position that they occupied before, that we could hardly believe a year had elapsed since we saw them there. The same Parrot with long list of his sayings was towards one end of the Corn Exchange, and hard-by was the same Parroquet still whistling "Merrily danced the Quaker's wife," as if he had never whistled it before. One Parrot in a voice of thrilling harshness perpetually shrieked "Fanny," and it was interesting to see how large a proportion of the fair sex among the crowd started responsive to the call. We were greatly struck by the generally fine condition of the more tender of the foreign birds. The aviaries of Mrs. Monk and of Mrs. Holmes were largely represented; they must, indeed, be a sight. We were specially struck with a lovely pair of Pekin Nightingales from the former, and with some sweet, tiny, "Zebra" Doves from the latter. The gorgeous foreign songsters by no means displaced our own British birds, of which there were seven particular classes, besides a large and most beautiful variety class, to which several extra prizes were awarded. The owner of a little Zebra-shell Parrot invited public attention in the catalogue to the fact, that "the bird never takes any water," and we could not help being a little amused at seeing an emphatic order on the cage that this element should not be offered it. We were once shown over a prison by an eccentric warder, who remarked, "The prisoners never take any wine." Upon our inquiring if it was ever offered them he replied, "Oh, dear, no, sir!" Perhaps the little Parrot would be no more averse to imbibing than some of the prisoners, if he had a chance. The Corn Exchange is a charming building for the Show, and well lighted. We were glad on the first afternoon to see it quite crowded.

Pigeons.—Jacobins.—The first-prize pair were excellent Reds, close in hood and good in chain. Second were Yellows; one of them a trifle long in beak, and neither very regular in hood; we suppose their colour attracted the Judge. We preferred the neat Red pair which were third and Mr. Baker's unnoticed pair. **Turbits.**—First were Silvers. This award was generally considered a mistake; the cock had a very suspiciously wanting peak, and the colour of their bars is poor. Second were very fine Reds, not an exact match in colour, but very good in head. Third Blacks, a capital cock unequally mated. We admired a young pair of Silvers shown by Mr. Salter. **Owls.**—First came a Silver pair, the cock good, but the hen very long in beak; the best judges seemed to think this award a mistake. Second were nice Blues, and third Silvers again. **Fantails.**—Mr. Baker carried off the three prizes with birds that are pretty well known now. First and third Whites, second Blues. This class was not equal to many in the Show. Mr. Cresswell showed a pair with very flat though somewhat broken tails. Magpies had two classes; we believe they are a *specialité* of the Oxford fanciers, and hence were particularly favoured by Reading neighbours. Both firsts went to Mr. Bailey of Magdalen College, Oxford. We hardly thought that his Blacks merited first honours, the hen being very "high cut;" but the Reds were a beautiful pair, as were Mr. Salter's second Yellows. In Barbs the three prizes went respectively to Blacks, Yellows, Blacks, all good. The Variety class was a large one. First were a beautiful little pair of foreign Owls. Two second prizes were awarded—viz., to Scandarons and Black Archangels. We could not see the beauty of the latter; they certainly had the Archangel form, but that draws one's attention to the want of the lovely prismatic copper hues of the ordinary birds. Third were reddish Frillbacks. We certainly thought some Trumpeters and foreign Owls hardly dealt with.

NANTWICH SHOW OF POULTRY.

This was held on the 4th and 5th inst., when the following prizes were awarded:—

DORSETING.—1, A. Darby. 2, W. H. King. 3, W. Copple. **COCHIN-CHINA.**—1, A. Darby. 2, H. Tomlinson. **BRAHMA POULTRY.**—Dark.—1, S. Lloyd. 2, J. Pownall. 3, A. Bamford. **Light.**—1, T. Edd. 2, R. E. Horsfall. **HAMBOURG.**—Penalised.—1, W. Speakman. 2, Mrs. Smith. **Sprangled.**—Cup and 3, Mrs. Fynn. **ANY OTHER BREED.**—1, Messrs. Silvester. 2, A. Darby. 3, J. Powell. **BRAND.**—1, B. L. Edwards. 2, F. Cooper. **GAME.**—Cockerel.—Cup, Sadler and Watson. 2, T. Burgess. 3, G. Walters. **Cock.**—Cup, Sadler and Watson. 2, R. Ashley. **Black-breasted Red.**—1, R. Ashley. 2, J. Chesters. **Brown-breasted Red.**—1, Sadler and Watson. 2, R. Ashley. 3, J. Chesters. **Other than Black or Brown-breasted Red.**—Cup, R. Ashley. 2, E. Winwood. 3, G. F. Ward. **Hens.**—1, J. Chesters. 2, G. F. Ward. 3, Sadler and Watson. **Pullets.**—Cup, T. Burgess. 2, S. H. Saxton. 3, Sadler and Watson. **Black-breasted Red.**—Owls.—1, C. Hughes. 2, T. Hasnall. 3, J. R. Pratt. **Brown-breasted Red.**—Chickens.—1, Sadler and Watson. 2, R. Ashley. 3, T. Billington. **BANTAM.**—Game, Black-breasted Red.—1, T. H. Stretch. 2, T. Foulkes. 3, W. Griffiths. **Game, Brown-breasted Red.**—1, J. Lee. 2, W. Baskerville. **Game, other than Black and Brown Red.**—1, Messrs. Farrington. 2, R. J. Goodwin. 3, J. Goulden. **Other than Game.**—1, H. Ashton. 2, and 3, J. W. Lloyd. **DUCKS.**—1, B. Edwards. 2, Miss Silvester. **TURKEYS.**—1, R. Beckett. **CHICKEN.**—1, R. Beckett. **Pigeons.**—Carriers.—1, J. Chesters. 2, W. Yardley. **Dragoons.**—1, W. Yardley. 2, A. McKenzie. **Pouters.**—1, W. Yardley. **Barbs.**—1, J. Chesters. 2, T. C. Troncher. **Nuns.**—1, W. Tidd. 2, J. Hinde, jun. **Tumbler.**—1, R. White. 2, E. PLURALITY OF QUEENS IN ONE HIVE.

LE FRÈRE RMAULD of Stauvelli, Algeria, has in *L'Apiculteur*, given an interesting account of the bees of Algeria, from which I extract and translate the following account of their queen-raising:—"The Algerian bees bring up an extraordinary number of queens at swarming time. I was much astonished when breaking-up the combs of a deserted hive at the great quantity of queen cells it contained. On one comb I counted thirty-eight, and five combs gave a total of 190, all sealed in that hive in March and April. All these cells were torn open at the bottom.

"There is yet another observation that very much surprised me. If anyone had told me I could not have believed it. All bee-keepers admit that two queens cannot rest in the same hive, that the piping of queens in their cradles determines the issue of the swarm, and that if the weather becomes unfavourable for many days the old queen destroys her rivals, which retards the swarming. Here is a fact to the contrary. On the 22nd of March I had a hive where the bees hung out very strongly; all the front of the hive was literally covered with them. On the 30th of the same month I determined to give a cap to that hive in order to excite the bees to work. Before touching the hive I listened and heard distinctly the piping of several queens. I then lifted the cover to replace it by one with apertures. In so uncovering the hive I found at the top of the combs three young queens already emerged. I left them, and put on the cap. That day the weather changed to wet and cold, and so continued until April 14th. Three days after in approaching that hive I heard the piping of three or four queens in the cap. Four days later the same piping made itself heard, and several others in the body of the hive, and five days yet later there were the same sounds, queens were therefore born all these twelve days.

"As the hive where these bees were hatched was half an hour's journey from my house I could not follow the observation. On the 14th of April the weather became fine, and we had on that day a dozen swarms issue, and when I revisited that hive all was quiet—the young queens had gone out with the swarm that stock had thrown. The brother who had the surveillance of that apiary had sent me the swarms without indicating which hives they came from."

It will be seen from the above that the season for bees occurs much earlier in Algeria than in Britain.—JOHN HUNTER, *Eaton Rise, Ealing*.

OUR LETTER BOX.

BEST SPOTS ON SPANISH FOWLS' FACES (J. P. C.).—The rust spots are caused by their being picked by their fellows. The cure is to remove the bird until it is quite healed. Frequent applications of compound sulphur ointment will cure the scurf of the comb. It is common to all fowls to pick any apparently raw spot, and when they have made it bleed they will positively eat the bird. Stranger still, the bird will stand still to be eaten. When birds make a sore it is from a vitiated state of the body, causing unnatural appetite. The treatment for it is, first an active purgative and then cooling food. Lettuce is very good.

SUNFLOWER SEED GROWING (F. W.).—Sow in April in rows 18 inches apart, and thin the plants to 30 inches apart. The seed will be ripe about August, and is given to poultry whole.

EARLY QUEEN-BREEDING (Stoodley Pike).—The very best book on early queen-breeding of which we know is by an American author of the name of Langstroth, but its cost is 10s. Can any of our readers recommend any other? Messrs. Trübner & Co., we believe, would supply you with Langstroth's book.

FEEDING BEES (W. H. Atwood).—We presume that your six stocks, saved thus far out of twelve, are in straw hives. As you must have plenty of empty combs from your lost stocks at your disposal, we think the simplest way for you to feed will be by taking a large flat comb and carefully filling the cells on one side of it with a syrup made of dissolved sugar. Set this flat upon the bottom board of the hive you wish to feed at a time twice a week, unless your bees are starving. In this case double the quantity will do, otherwise it is better to feed a little and often at this time of year. It will do no harm if you keep this up for a couple of months. Your bees will amply repay you for this trouble. If your hives are in wooden boxes you have only to make an hole of wood exactly the size of your box about an inch thick. On the whole we think this mode of feeding about the best of any of the systems which have been recommended.

MOULDY COMBS (Carolus).—Cut all the mouldy combs out of your hive as soon as you can conveniently. Keep both the hive and the board free from moisture in future, otherwise more combs will become mouldy.

HOW TO SELECT GOOD STOCKS (Wm. Talbot).—If you have courage enough to turn up hives and examine them internally, you may easily select three of the best out of the dozen of hives belonging to your friend. Go to his garden before the bees are astir, gently and quietly uncover all of them without disturbing the bees at all. Then gently lift (one by one) the hives off their

boards, and turn them up, so that you can see the bees sitting amongst the combs, and count the number of clusters or seams of them in each hive. If small hives have four seams each, about as large as a tinsup saucer, they may be considered in pretty good condition as to population at this time of the year. The most populous hives now, other things being equal, are the best. In examining hives thus you will see at a glance whether their combs are old or young, and whether the hives are full of combs or not. Young are better than old black combs, and hives filled or nearly filled with combs are preferable to those half empty. You are not able to detect the disease of foul brood, even if it exists in any of the hives. If the hives are not nailed to their board the examination now suggested may be completed in six or seven minutes. Mark or put a stone on the flight boards of those you may deem the best. If the hives are fastened to their boards and cannot be turned up without first disturbing the bees, blow some smoke into the hives before you examine them. Honey stores, though of less importance than population, should not be forgotten in turning the hives up.

GALVANIZED IRON VATS (Miss H.).—These must not be used to hold cider. The white metal coating the iron is zinc, with which the acid of the cider would combine and form a salt probably poisonous.

REMARKS.

2nd.—Rain in early morning, but fine before 10 A.M.; a bright beautiful sunny day, and a starlit night.
3rd.—White frost early; fine all day, at times bright, but not near so fine as its predecessor.
4th.—Fair all day, but windy and cold.
5th.—Snow in early morning, but fine by 10 A.M., and so continued all the day but windy and cold at night.
6th.—Fine morning, but a little snow at 1.30 P.M., at 5, and at 9 P.M.; moderately pleasant in the early afternoon.
7th.—Fair, but not bright in the morning; rather dull and cold all day.
8th.—White frost early; rather overcast all day, with frequent very slight falls of snow.

A somewhat wintery week; frequent falls of snow, but not of any depth, nor lying on the ground.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 9.

A FAIR amount of business has been done during the week with no alteration in prices. A large arrival of St. Michael Pines is to hand in splendid condition, making the sale of English fruit very difficult. Kent Cobs are realising advanced prices.

From observations taken near London during forty-three years, the average day temperature of the week is 46.1°; and its night temperature 31.8°.

CAULIFLOWERS AND BROCCOLI.—No. 1.

BEWILDERING to many must be the array of names which would seem to be needed to satisfy the requirements and fancies of growers of these vegetables. The lists furnish names as numerous as are the weeks of the year. If the "sorts" would fall into profit naturally during each of the weeks they would be of great value, for sweet white heads are ever in demand.

I have had to supply Cauliflowers (including Broccoli) "all the year round" without any forcing appliances, and for seven years I have not been without a dish when it was wanted. To effect this I have relied on three sorts of Cauliflowers and four of Broccoli. Cauliflowers: Dwarf Mammoth (Improved Early Erfurt), Walcheren, and Veitch's Autumn Giant. Broccoli: Snow's Winter White, Adam's Early White, Knight's Protecting, and Cattell's Eclipse.

By sowing Cattell's Eclipse in June, and growing on a north border (or growing anywhere and laying the plants in a north border in November), heads have been produced until the middle of the following June. By sowing Dwarf Mammoth Cauliflower in August and protecting the plants on a south border, they have produced heads in June before the Broccoli on the opposite side of the garden have been beheaded. The Cauliflowers have united with the Broccoli in early summer—a point which should always be aimed at.

The Cauliflowers I have said are ready in June; they have continued until the middle of January; by that time Snow's Winter White Broccoli has always been ready for cutting. The Broccoli has again met the Cauliflower in winter, which is another point which we should always endeavour to accomplish.

Those two main points attained the rest is not difficult, except the summer is unusually hot and dry, when it is no easy matter to provide a late summer and autumn supply. That has occasionally been my greatest difficulty. I never could have succeeded without that heat-defying sort Veitch's Autumn Giant, which is one of the most valuable introductions of recent years.

Having mentioned the primary points to attain, I will now state how they have been attained. The first and last crops of Cauliflowers are especially important. Seed for the first crop has been sown in August, and the plants when large enough were planted 9 inches apart on a south border. As winter approached boards were affixed on their edges at the back and front of the border, and spare lights laid across and further covered as needed. In the spring every alternate row was removed and every alternate plant in the row remaining, leaving the plants at 18 inches apart. These were encouraged by a dressing of nitrate of soda or guano—preferring the former—and were thoroughly watered, and the ground heavily surface-dressed with manure. That always brought out the heads in June. But to make sure two sowings were always made in September, one about the 10th and

the other about the 20th, and the south-border plantation was always a large one—much larger, indeed, than required if every plant could be depended on; but they cannot, and the more uncertain the crop the greater must be the margin for emergencies.

That is where many fail; they do not provide for emergencies and the fickleness of seasons. "Plant more than you want" is my kitchen-garden motto, and especially where it can be done without robbing the ground. In the autumn ground is vacant, and it is easy to pull up surplus Cauliflower plants in spring in time for planting Potatoes, and nothing has been lost but half-a-day's work of dibbing-in the plants. That practice has always made sure of the first crop, and now for the last.

Good sowings of Dwarf Mammoth and Walcheren were made about the 20th and 30th of June—two sowings again, mind. When the plants were ready for planting the south border was clear; the early Potatoes had been taken up and the Pea haulm cleared off. The ground not being wanted, why not fill it with Cauliflowers? It has been filled. Some, in spite of every attention, will "button," but when once the autumn rains fall the plants grow like magic, and will just be in time to commence forming small heads in November—heads, however, to be killed if not protected. Here the advantage of a large plantation is again felt. Select the most promising plants, dig them up and lay them in closely in cold spare frames, water them and further protect from frost as needed. These plants will supply excellent small heads for two months. After the frames are filled, or, if there are none, lay the plants in a convenient place and cover them with leaves—autumn leaves. I have cut Cauliflowers in January from under a foot of leaves as fine as those from the frames—pure white heads 2 to 3 inches in diameter—just the sort for a gentleman's table. The great point in these two crops is to "plant more than you want," and if you have plenty of Cauliflowers when your neighbours have none, no one will find fault with your having occupied vacant ground in such a wholesale manner.

The first and last crop of Cauliflowers being disposed of, I now turn to the first and last crops of Broccoli—the crops between these requiring no special care. The first thing to do is to procure Snow's Winter White Broccoli true. There are many spurious stocks. Sow the seed in March thinly, so that the plants will grow sturdily, and transplant when large enough in an open airy place. It is essential that the plants have ample room to develop themselves, and they should not be closer together than 2½ by 3 feet. A short woody, not a long sappy, growth is the main point to secure, and the sooner and better this is done the earlier will be the produce.

It is a singular fact, and one which can only be arrived at by experience, that this valuable Broccoli will produce heads earlier when the plants are grown in a perfectly exposed place, such as an unwall'd garden, than they will if grown on the warm south border of a walled garden. I have repeatedly had plantations on both sites, and invariably in favour of those which had been exposed. These latter perfected a more woody growth than the

former, their stems matured sooner, and their heads formed earlier. When planted out early and grown thinly in an open place (if I had the choice I should select the middle of a fifty-acre field), the stems of the plants are short and easy to protect (if protection is necessary) by packing round them stubble or other strawey refuse, and these plants will never fail to produce heads in January, and not infrequently I have cut them before Christmas. In severe weather the heads must be protected by turning the foliage over them, enclosing also a handful of hay.—R. FISHER'S PUPIL.

ROYAL HORTICULTURAL SOCIETY.

THE adjourned Annual General Meeting of this Society was held on Thursday afternoon in the Council Chamber, South Kensington. The Right Hon. Lord Aberdare, the President of the Society, occupied the chair. The proceedings were to a great extent characterised by the same want of harmony which has marked for some length of time the public meetings of the Society, and indeed at one stage of the business—during Lord Bury's remarks—the noise and interruptions threatened to put an end to the proceedings, and it may be said that only the firmness of the noble Chairman prevented the meeting from ending in confusion.

Amongst those of the Council present were the Hon. and Rev. J. T. Boscawen, Mr. H. Webb, Dr. Hogg, Mr. Haughton, Lord Alfred Churchill, Dr. Denny, Sir Trevor Lawrence, M.P., Col. Trevor Clarke, Mr. Kellock, Mr. Campion, &c. Amongst those of the general body of Fellows—of whom there was a good attendance—were Mr. Shirley Hibberd, Sir Alfred Slade, Bart., Sir Peter Pole, Lord Bury, Admiral Hornby, Mr. Grote, Mr. G. F. Wilson, Dr. Masters, Mr. Godson, General Scott, Mr. Guedalla, Mr. Smee, Mr. Pinches, Mr. Bateman, Mr. Edgar Bowring, &c.

The Annual Report, which was taken as read at the meeting of the previous Tuesday, was circulated through the room. [This Report was published in our last issue.]

THE CHAIRMAN, in opening the business of the meeting, said—I think it only right that I should first of all explain our adjournment of this our annual meeting from last Tuesday until to-day. As you are aware it was imperative on the Council to call the meeting for the 8th in accordance with the bye-laws of the Society, but as on that date Her Majesty was announced to open Parliament in person, and as a full attendance of the Fellows could not be expected on such a day, we resolved merely to hold the meeting *pro forma* in order to adjourn over until to-day. An advertisement to this effect was inserted in the papers, and the meeting was held. I was not present myself, but I believe there was but a small attendance of Fellows. I will now explain what took place. The Council, in accordance with their public notice, wished merely to formally adjourn the meeting without transacting any business whatever; but some of the Fellows present maintained that in accordance with the Charter of the Society it was imperative on the meeting then convened—being, as it was in fact, they said, the Annual General Meeting—to proceed to the election of members of the Council in the place of those who had retired since the last special general meeting. This they actually did proceed to do, but I would ask you to understand that the members of the Council strongly protested against such a course being adopted, and what followed was done against their wishes and in the face of their opposition. They held that the adjourned meeting would be quite competent to transact the business set down in the ordinary course of events for Tuesday, but their objections were overruled by the majority of the meeting, and the election of members of Council was gone on with. The Report, however, was only taken as read, but was not adopted, and therefore it will be perfectly competent for this meeting to accept or reject it as you think fit. It is my business, then, as Chairman, to move the adoption of the Report. I regret very much indeed, in the present state of feeling amongst the Fellows, that it is impossible for me to enter at this time into the subject which no doubt interests you most—that is, I mean as to what has been done by the Council since our last meeting. As you are aware, a discussion took place at that time as to the alterations in the privileges of the Fellows which the Council considered necessary in order to place the Society on a firm basis as regarded the payment of our debt and the future income of our Society. We found so much opposition to the new privileges that it was at length agreed we should take back the rules and revise them as far as possible. This the Council consented to do, and a considerable alteration has been made; indeed, I may say that at another time I could venture to show that very important alterations for the benefit of the Fellows have been made in the new scale of privileges, but I cannot do so at present because of a certain circumstance which has occurred. Only yesterday a Fellow handed in a notice to the Council that he would move to-day a resolution, the effect of which will be, if it is successful, a vote of want of confidence

in the Council, or, in other words, we will be called upon to resign. Now, there is an excellent rule in Parliament which says that votes of non-confidence shall have precedence over every other question, and that no other business can be brought before the House until such vote has been disposed of, and I would submit to the meeting that on this occasion the same course should be adopted. It is useless, as you will see, for us to discuss the revised privileges or the future policy of the Society when we have a thing of this kind hanging over our heads. It will be quite time enough for us to talk of what we may or may not do in the future to forward the interests of this Society when the vote of the meeting is taken, and we find whether the majority of those present have confidence in the Council as at present constituted, or whether you are disposed to deprive us of the powers we now possess. I therefore hope it will be the pleasure of the meeting that priority shall be given to the resolution of which Mr. Hardcastle has given notice, so that we may at once proceed to the disposal of the business which has called us together [hear, hear].

MR. HARDCASTLE said he must confess it was with considerable surprise—after understanding from the notice which had been issued by the Council that the meeting of Tuesday last was merely to be a *pro forma* one—that he had been since informed that most important business had been transacted there. Several Fellows had been elected to the Council, and further that the Report had been carried [no, no].

THE CHAIRMAN.—I think I gave it to be understood that the Report was not adopted; and as to the election of Fellows the meeting would have it so, although the members of the Council strongly protested against such a course. It is for this meeting to accept or reject the Report.

MR. HARDCASTLE would accept what the noble Chairman said regarding the Report. He agreed that any discussion on the privileges should be postponed until the opinion of the meeting was taken on his motion. He would now come to the question which he had to bring before them. The policy of the present Council up to that time—but not the policy which had been sent round a few weeks since—had been one of inclusion. It was the duty of the Council to secure for the inhabitants of that part of the metropolis all the enjoyment they could consistently with the policy of the Royal Horticultural Society; but their new policy was diametrically opposed to such a course. In fact, the scientific Fellows wished to get as much as they could out of the South Kensington Fellows, and give them as little as possible [hear]. The question then came, Were the Fellows to submit to such treatment? [no]. For his own part he would strenuously oppose a policy of the kind. He did not wish to express himself with any feeling against any member of the Council. He did not wish this to be an excited meeting, as many of their gatherings were; but he could not but condemn the policy they wished to force on the Society. He therefore intended to move that the Report should not be adopted, and that the present members of the Council should be called upon to resign. No doubt the Council had the best intentions, and had done the best they could, but they had adopted a very bad mode of raising the fortunes of the Society [hear]. Looking at the past history of the Royal Horticultural Society, it could at once be seen that it had from the earliest period been divided into two factions—the scientific horticulturists, or gardeners to use an older name, and the non-scientific horticulturists, or those who admired a pretty garden without being learned in the names of the plants or shrubs. Now they all knew very well that the Society could never support itself as a purely horticultural society, and the scientific or gardening portion had failed from the first to make the gardens a financial success. It had been so in the old days, when the Chiswick Fellows depended for a great portion of their income on the fêtes which they gave from time to time, and it was so at present in regard to their gardens at South Kensington. One thing, then, was very certain—if the horticulturists or gardeners were bent on carrying out their own objects without regard to the interests of the residents, or if the residents were bent on carrying out theirs, the Society would surely fall to the ground. A change of policy which would make the gardens a pleasant resort for those who resided in the neighbourhood could alone save the Society from absolute effacement. With reference to the proposed changes in their privileges he would say a few words. A gentleman who entered the Society as a twenty-guinea or forty-guinea Fellow paid his money for certain privileges, but after a little time he suddenly found a great portion of them cut off. What was he to do? An annual Fellow could leave the Society without sustaining any pecuniary loss, but if a life Fellow did so he forfeited what he had paid. Did they think if such a policy was adhered to that many would be found willing to join the Society? He thought not. He was just reminded that within the last year they had lost £1600 of income. Under such circumstances they must consider what was best to be done. He thought the only thing they could do was—he did not like to use the word “turn out” the Council, but he would say “reconstruct” it. If they did so what were they to do next? If he had a list of names to form a Council

prepared he might be told he wished to force these men down the throats of the Fellows, while if he had not a list they might feel inclined to say, "Why do you complain when you are not prepared to meet the difficulty?" So of two difficulties he would choose the lesser one, and in the event of their succeeding in the motion they would submit a list which he held in his hand. He would just say that in that list their present noble and able President was retained as the head of the Society, and several of the present Council would also be proposed for re-election. For his own part he was inclined to think that the scientific Fellows should be rather on the Committees of the Society, where their technical knowledge was required, than in a majority on the Council. In conclusion, he hoped that the resolution he was about to propose would be accepted by the meeting—"That the Council, including those members who were elected on Tuesday last, be requested to resign." [hear, hear, and no, no.]

Sir ALFRED SLADE was much surprised at what had taken place at the meeting on Tuesday. Why were not the Fellows informed that business would be transacted? How was it that Fellows had been elected and the Report read? He protested against—

The CHAIRMAN.—I have already explained the matter twice, and will if you like do so again for the third time. The meeting was called by the Council in order to adjourn until to-day. It was not their wish that any business should be transacted, and what the majority of the meeting insisted on doing was done in the face of their strong protest. Those who had so acted honestly believed, no doubt, that they were right in electing the Fellows, as they seemed to be under the impression that such election could only be conducted at that meeting.

SEVERAL FELLOWS.—We protest against Tuesday's meeting. Mr. PINCHES, who rose to second Mr. Hardcastle's motion, said he regretted very much what had taken place on Tuesday. He did not censure the Council, but rather those who had acted in such bad faith. With regard to those who had been elected to fill up the vacancies in the Council, he should have thought a sense of delicacy would have kept them from taking their seats until at least the present meeting would have expressed its opinion on the question.

The CHAIRMAN.—This meeting could not have prevented them taking their seats. In order to do that, seven days' notice against the election would have been necessary.

Mr. PINCHES would only leave it to their sense of delicacy. Had he been elected under such circumstances he certainly would not have sat at the Council board; but he would not put himself up as model of propriety for others to follow. In supporting Mr. Hardcastle's motion he did so for many reasons. The Society was in an infinitely worse position now than it was three years ago. Their faith had been shaken in Lord Bury's Council when they saw its repeated failures to effect a satisfactory solution of the grave difficulties in which the Society was placed, and therefore they had looked forward with hope to what the present Council might propose to do. But the Council had not been in office many weeks before the Fellows heard that the old process of disintegration was at work, and he had been informed that several gentlemen of high public character had lately left the Society altogether; while since their last general meeting two prominent members of the Council had resigned (Admiral Hornby and Mr. Grote). He took the position of Lord Aberdare as that of a Prime Minister trying to retrieve the fortunes of the country at the head of a coalition ministry. It had often been said that England had no faith in coalition cabinets, and for his own part he would confess to having very little in a coalition council [hear, hear]. The measures they proposed up to the present time could not keep the Society from inevitable ruin and decay. He considered there had been some sharp practice in regard to the new regulations. Sufficient time was not given for objections to be lodged against them. Were the new privileges accepted it was hard to see how the Fellows could be kept from seceding, or in what way the outside public would be attracted towards the Society. The twenty-guinea and forty-guinea Fellows were especially to be pitied, called on as they were to surrender a great portion of their privileges without getting anything in exchange. The shows had greatly diminished in value, and the gardens were in a state of chaos. He would admit that the Council had cut down the expenses, but it only reminded him of the story of the parsimonious owner of a horse, who, having in the ingenious exercise of his economy, brought the animal down to a corn of a day, found himself without a horse just as he thought his experiment a success [laughter]. The Society would soon be, if such disastrous economy were pursued for any length of time, in the position of the horse-owner, and find themselves without a garden [hear, hear]. If the resolution before them was not carried the Society would die of inanition. He believed that Mr. Freake had proposed to build a school of music and hand it over to the Society, as well as lend them £5000 to help in clearing away their debt. Admiral Hornby had informed him of this, and he had considered it a very rosy prospect for the Society; but

he was afraid Mr. Freake would now be likely to withdraw his offer when he saw members of the Council resigning, believing, as no doubt he did when he made it, that the new Council would have been a permanent one. Perhaps it might be possible for Admiral Hornby to give them some explanation as to why he had thought it necessary to leave the Council. Was it that he found it impossible to get on with his colleagues, or did he find it necessary to mark his disapproval of the revised privileges by resigning? It was to be hoped that some plan of joint action would be found whereby all parties could unite for the common good. Were he asked for a scheme by which the fortunes of their Society might be redeemed, he confessed he would be in the same difficulty as the Council; but it was their business as the governing body to find a proper way out of their embarrassments. At the present time it was necessary that the Council should be called upon to resign, because they had altogether failed in their mission. Their privileges should be given back to the Fellows, and inducements held out to the residents round about to become members of the Society. What these inducements should be it was not his business to say, that should be left to the Council to determine. It was to be hoped a Council would be found which would work amicably together. In conclusion, he hoped that their President would remain at the head of affairs, because he (Mr. Pinches) had every confidence in the noble lord's ability to bring their difficulties to a successful issue, and he therefore hoped his lordship would be re-elected [hear, hear]. He had to complain of his name being printed in the Report as an auditor for the present year. He had withdrawn his name in consequence of finding that the accountants who usually kept their books had resigned their office.

The CHAIRMAN.—We found it impossible to strike out your name, as the notice was too short. The rule is to give seven days' notice.

Mr. PINCHES.—That may be; but some one else might have been found to take my place.

Mr. ALFRED SMEE rose as a gardener. He believed that until the Society obtained a new Charter they could never hope to work together as a "Royal" Society should. He would characterise the existing Charter as one of the worst and most impracticable documents that had ever been prepared in this country. Under it they could never prosper, but would continue to go on in the same idiotic way as at Tuesday's meeting. Another reason why they could not get on was that they had forgotten the original objects of the Society. He would ask, Did scientific societies usually mix themselves up with skating rinks? ["question," and cries of "time"]. One sure sign of their decay was that they did not publish any journal now. For his own part he did not care whether the South Kensington Gardens were built on or not. Who would care if his own private garden were destroyed? Why should the horticultural Fellows throughout the country be saddled with a garden which was ruining the Society? ["time"]. Let them consider that twenty thousand plants were annually consumed in the dreary wilderness appended to that building which was called in mockery a garden. He did not think if they put in any number of councils that they would be a bit the better for it [cries of "time" and "chair"].

The CHAIRMAN considered that Mr. Smees was quite in order.

Mr. SMEE then went on at some length to say that there were three parties in the Society to be consulted, and until they agreed to work amicably together the Society would go on from bad to worse.

The latter portion of his remarks were frequently interrupted by cries of "time" and "question," and the Chairman had again to interfere in order to get the speaker a hearing.

Sir PETER POLE agreed with Mr. Hardcastle's motion, but he would not say whether the Council were fit for their places or not. Several members of the Society had asked him to make some remarks regarding the new privileges; for instance, the ticket given to a four-guinea Fellow was not transferable.

The CHAIRMAN.—The ticket can be given to anyone.

Sir PETER POLE.—But suppose my daughter wishes to enter the gardens; she cannot do so on my ticket.

The CHAIRMAN.—There is nothing to prevent your daughter or anyone else from entering the gardens. She could come in as a nominee.

Sir PETER POLE said he maintained that under the new rules he could not lend his ticket to anyone, and such was the opinion of his friends [hear, hear].

The CHAIRMAN.—No doubt the power of transfer has been taken away, but you can meet the case by purchasing for £1 forty admissions [oh, oh]. Of course our whole policy is a restrictive one.

Lord BURY, who at this stage of the proceedings entered the room, then addressed the Chair as follows: I must apologise for my seeming discourtesy to the meeting in being so late, but I have only just left a meeting in the City. I think the gentleman who has just sat down has trailed a red herring across our path. I consider that the motion which has been put to the

meeting by Mr. Hardcastle should be kept before us, and that the subject should not be wandered away from. Now there is one preliminary thing which I would like to say, and about which I wish for information. How was it that business was transacted at the meeting on Tuesday last, when the Council announced that it would only be held *pro forma*? ["time"]. In honour no important business could have been transacted in the face of such an announcement. I am surprised —

The CHAIRMAN.—This has all been said by previous speakers. Lord BURY.—Then I must say it again [cries of "no" and "time"]. No business should have been — [Here several Fellows protested against Lord Bury taking up the time of the meeting in going over the same ground as previous speakers.]

The CHAIRMAN.—Surely this is not the question before the meeting. I must ask my noble friend whether this is keeping to the resolution.

Lord BURY.—I will protest against the proceedings of Tuesday last [cries of "time" and "divide"]. I will obey the ruling of my noble friend and keep to the resolution. I consider that the great reason why the Council should be called upon to resign arises from the proceedings of last Tuesday [continued cries of "time" and interruption].

The CHAIRMAN.—But as I have already explained several times before, what took place at the meeting on Tuesday was done in spite of the Council, and how could they prevent it?

Lord BURY on again essaying to address the meeting was met by shouts of "time" and "divide, divide," and general interruption.

Lord BURY [turning excitedly to the meeting].—You needn't halloo at me in that way! [Confusion.] Lord Bury continuing—I confess I am surprised to see Lord Alfred Churhill sitting among the Council. It would have been far more decent for him to have stayed away after the peculiar manner in which his lordship was elected to the Council on Tuesday [continued cries of "time" and "chair"].

The CHAIRMAN.—I would advise my noble friend to keep to the resolution.

Lord BURY.—If I am allowed to say two consecutive sentences you may understand what I have to say. I do not wish to say anything against my noble friend. I hope he will remain in office at the head of the Society [cries of "time."]. What I want to say is in condemnation of those members of the Council who allowed the election to take place on Tuesday last. I say that the fact of their allowing it was an indication of incompetency on their part ["oh!" and disturbance.] My noble friend has said he did not agree with the course pursued by the Council on that occasion [continued cries].

The CHAIRMAN.—I protest against this. I never said I disagreed with the Council. They did their best to keep faith with the public. I consider your lordship is not speaking to the resolution [disturbance].

Lord BURY.—I have been speaking to the resolution. Who put the resolution to the meeting, and why did he do so? The fact that the Council allowed the election on Tuesday was an indication of incompetency on their part.

The Hon. and Rev. J. T. BOSCAWEN explained that he had occupied the chair at the meeting referred to, and had no other alternative, according to the Charter, but to put the resolution proposed to the meeting [hear, hear, and no].

Lord BURY.—The fact of the Chairman submitting an informal resolution to the meeting is another reason why a vote of want of confidence should be carried [interruption]. The conduct of the Council since its election has been out of harmony with the interests of the Society. They have done nothing to extricate us from our difficulties [continued cries]. His lordship concluded by supporting the resolution.

Mr. SHIRLEY HIBBERD would let the meeting divide on the question by proposing an amendment. Mr. Hardcastle, who was about to retire from the Society, wanted to leave it in a state of revolution.

Mr. HARDCASTLE.—I did not say I would leave the Society.

Mr. S. HIBBERD.—The gentleman and his friends wished again to have the Society in a state of revolution. Why did they want to oust the present Council? Because, as the proposer of the resolution said, "they had done their best." In fact, that gentleman and his party did not know what they were about. They were rehearsing the performance of three years ago, but had forgotten their parts. Lord Bury and his friends were in a fog as regarded the actual financial position of the Society. The gardens, for which no one paid, always kept them in difficulties, and now they had £6000 of debts. The Council had tried to re-arrange the terms of fellowship, a course which was called for by public opinion and common sense [hear, and no]. For his own part he considered the revised privileges were a great deal too easy for the residents of South Kensington, they should be made to pay not less than ten guineas each yearly. The income of the Society had to be raised by some means or other, and the new scheme proposed by the Council should at least have a year's trial. It was monstrous that the gardens should be kept up for the amuse-

ment of the local Fellows at the expense of country Fellows. He objected altogether to the motion, which was brought forward for the purpose of again throwing the Society into an unsettled state [no, no, and hear, hear]. He would conclude by moving as an amendment, "That the ballot of Tuesday last be confirmed, and the Report adopted" [hear, hear, and dissent].

Mr. HARDCASTLE.—I submit that that is not an amendment to my resolution.

The CHAIRMAN.—Well, I hardly think it is, but it can be made an amendment by giving a direct negative to the motion. It will come to the same thing if the proposed amendment is altered to "that the words after 'that' be omitted," and the words, "the Report be adopted" substituted. I think that would meet all that is required.

Mr. HIBBERD accepted the alteration.

Admiral HORNEY.—May I be permitted, my lord, to answer the questions asked with reference to my retirement from the Council? Would my doing so be a breach of faith?

The CHAIRMAN.—It is for you to act on that point as you think proper. Of course you can only speak for yourself, and if your remarks are limited to that I do not see any harm in your explanation.

Admiral HORNEY then proceeded at some length to explain his resignation. He would say for himself that he had worked harmoniously with the Council, and there had been no quarrel between them. He should say, however, that after joining the Council he found himself in a false position and in a hopeless minority. He disapproved of much that had been done. For instance, he was opposed to the revised privileges which had been issued.

SEVERAL MEMBERS OF THE COUNCIL.—Why, you voted for them.

Admiral HORNEY said it was no secret that Lord Aberdare and himself protested against them. He believed the revised privileges could not be worked for the benefit of the Society; they were simply impracticable. Being of this opinion he had felt it his duty to resign, as also did Mr. Grote. They were altogether unable to do what they thought right, and so considered it best to retire.

Mr. GEORGE WILSON then seconded the amendment. They had had enough of turning out Councils. He would say, Pray do not make matters worse than they are by turning out the Council.

Mr. PETER LIGGINS would support the motion. One proof of the decay of the Society was the comparatively small attendance at the meeting that day. A few years ago the room would have been crowded by Fellows who wished to hear the President's statement. In order to show how the affairs of the Society were mismanaged he would bring a certain circumstance before the meeting. A lady, whose name it was unnecessary to mention, had written to the Council complaining of the revised code of privileges, and in reply received a letter from the Secretary accepting her resignation. Now, she had not tendered her resignation and had no intention of doing so.

A MEMBER OF THE COUNCIL said this was the first they had heard of the matter.

Mr. LIGGINS went on to say he could give the name. He brought the case forward to let them see how recklessly the income of the Society was thrown away [cries of "time" and "sit down"].

The CHAIRMAN said the Council knew nothing whatever about the letter or the lady. The last speaker must have been misinformed as to the facts.

Mr. EDGAR BOWRING, Treasurer to the Royal Commissioners, spoke as to the urgent necessity for a vigorous effort to be made in order to raise the income of the Society to £10,000 per annum, so as to meet the claims of Her Majesty's Commissioners.

Mr. GODSON wished to know how it was that the Council did not vote at Tuesday's meeting, and thus defeat the object of those who wished to force new members on the Council [cries of "divide"].

The CHAIRMAN thought it was unusual for the Council to vote.

Mr. GODSON said they could have done so [cries of "time," and "divide"].

The CHAIRMAN considered the Council could not have voted. In any case they were in a minority ["time"].

Mr. BATEMAN was opposed to the motion [continued cries]. It was wrong to be always changing their Council, and if the resolution was successful they would only be adding to the embarrassments of the Society [cries of "divide"].

The discussion closed at this point, the meeting evincing considerable impatience to have the vote on the resolution taken.

The CHAIRMAN.—It is now my duty to put the resolution and the amendment to the meeting, so that the question may be decided, but before doing so I would say a few words. Before my own fate or the fate of the Council I would consider the fate of the Society, and I would ask you to think what may be the result if the motion is successful, or even if it is not. Whether you are willing or unwilling that it should be so—and no doubt there are many present who are unwilling—the

fortunes of South Kensington and Chiswick' are united, and united they will remain unless you obtain a change in the Charter. Now, supposing this vote calling on the Council to resign is passed, I do not know what may be done. As you know the Council need not resign their seats unless they wish to do so, you cannot compel them to resign. Of course a Council acting after such a vote would have but little power, and would only be a Council in name. The only way a Council can be got rid of is to serve a notice of incapacity against each individual member seven days before the annual meeting. But I shall leave the Council to act as they think fit; I can only speak for myself, and cannot say how they may feel disposed to act. My opinion, however, is that whether they remain after an adverse vote, or whether they get a vote enabling them to remain, the difficulties of the Society will be immeasurably increased, and they will find their position far from being a pleasant one. If they do retire, the succeeding Council need not hope to have an unanimous constituency. Indeed, I am of opinion that the removal of the Council of 1873 brought on disunion and disorder [hear, hear]. It will not be until our large constituency agree to act together with unanimity that we can hope for any success in altering the position of the Society. For myself I am not afraid of any vote, and would be quite content to give up the onerous position I now hold, but I should be ashamed of myself did I think of leaving the Society in its present difficulties. Admiral Hornby has said that the Council was not unanimous on the question of the privileges; but I must say that when I was asked to join the Society in order to help in doing something to retrieve its fortunes, I was told that there was a strong spirit of self-sacrifice on the part of the Fellows, so that the desired end might be obtained. When, therefore, with the present Council I accepted office, I found it to be the almost unanimous opinion of my colleagues that the transferable tickets were the cause of much loss to the Society, and ought to be done away with. It is quite true that Admiral Hornby and myself would have preferred a modification commonly called a family ticket, but we were overruled, and bowed to the will of the majority. After the discussion at the last general meeting which took place on the new scale of privileges then submitted to the Fellows, Admiral Hornby and Mr. Grote were of opinion that some very important modification should be made in order to meet the views of the general body of the Society. It was, however, the decision of the majority that the general principles of the amended code of privileges should be retained, and the two gentlemen referred to consequently retired. I will now make a suggestion just as if I were in the body of the hall—simply as a Fellow, and not as your President. It is, that instead of declaring warfare between the Council and the Fellows, some attempt ought to be made to agree on some form of action which will command general consent. With that view I would further suggest that this meeting be adjourned, and that the list of members whom Mr. Hardcastle is about to propose as a new Council be formed into a committee, who can associate themselves with the Council, and endeavour to agree to an attempt being made to find a mode of harmonious action, so that we may all work altogether. I trust after throwing out these suggestions that the resolution will not be pressed. Already the half year's rent is due, and I confess we are rather anxious as to how the money is to be obtained. In the present unsettled state of our Society those who are inclined to lend money are almost afraid to do so, though of course they have the Commissioners to see to the repayment; and then, too, the February interest on the debentures is overdue. I am quite satisfied that a momentary triumph over the present Council will lead only to greater difficulties in the future. Let the meeting be adjourned, and a fresh series of propositions can be made from the Council to the Fellows. I make all these suggestions not on my account, because, for my own part, I should be very glad indeed were I relieved from my somewhat difficult position; but, as I have said before, I really do not wish to leave the Society in its difficulties. I earnestly trust that Mr. Hardcastle will not press his motion [applause].

Mr. HARDCASTLE would not consent to withdraw his motion. The key of their financial position was the increase of local Fellows. The policy of the Council was opposed to such an increase and would effectually prevent it. The vote of the meeting should be taken as to whether the present Council ought to remain in office or not. If they were successful it would be for the Fellows to say whether they should adjourn.

The CHAIRMAN.—Then it only remains for me to put the resolution. The amendment can be put as a substantive motion. Those for the motion could say Aye and hold up their hands.

His lordship then put Mr. Hardcastle's resolution to the meeting with the following result:—

For the motion	82
Against	45
Majority	13

The result was received with cheers.

Mr. GODSON moved the adjournment of the meeting.

The CHAIRMAN thought that his suggestions with regard to the appointment of a committee ought to be considered. Had Mr. Hardcastle left the room? Perhaps he would act on a committee.

Mr. HARDCASTLE having returned, said he should be happy to do anything he could for the good of the Society. He should have no objection to serve on a committee.

The CHAIRMAN.—Would Mr. Pinches join the committee?

Mr. PINCHES did not object. He should, however, like it to be understood that his name was not amongst the list held by Mr. Hardcastle.

A committee consisting of Mr. Hardcastle, Mr. Pinches, Mr. G. F. Wilson, Mr. C. J. Freahe, Mr. A. Grote, and the Hon. R. W. Chetwynd, was then appointed to confer with the Council on the state of affairs.

Mr. VITCH having moved the adjournment of the meeting to that day fortnight,

Mr. PINCHES proposed a vote of thanks to the noble Chairman for his able conduct in the chair, and the meeting then separated.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 16TH.

FRUIT COMMITTEE.—Henry Webb, Esq., in the chair. Mr. Potte, the Gardens, Sudbourne Hall, sent two varieties of Dandelion; that grown in France for salads, and the common English type, also the Barbe de Capucin or Chicory, and the variety sent to the last meeting named Witloof. Mr. Potte finds the above very useful for salads in the winter, and as shown by him at the meeting were very creditable productions, well deserving the cultural commendation conferred by the Committee.

Mr. Monro of Potter's Bar showed twelve fruits of his excellent winter Cucumber Duke of Edinburgh, for which he received a cultural commendation. The fruits were of good flavour and of a very useful size for a gentleman's table. A dish of Onions was sent from Mr. F. Bonnal, but was passed as being an ordinary stock of Brown Globe.

Harrison Weir, Esq., Weirleigh, sent a dish of a seedling Potato, King Harry, second early. It is a good variety of a prolific character, but was passed by the Committee. The same gentleman also sent a dish of Matthew's Bliza Pear, which proved to be Josephine de Malines; a good variety for the season. A cultural commendation was also voted to Mr. Weir for a dish of well-kept highly coloured Blenheim Pippin Apples, the finest which we have seen for some time.

Rev. George Kemp, Sevenoaks, Kent, sent a dish of Joly de Bonneau Pear. It was slightly astringent, but of a brisk aromatic flavour; it was thought to be a good late sort, but as exhibited did not merit special notice.

A dish of seedling Apples was sent by Mr. J. McLaren, Ash Vale. It was undistinguishable from Cellini, and was passed by the Committee. Messrs. Lucombe, Pince, & Co. of Exeter sent Apple Gidley's Pearmain, a seedling from Cornish Gilliflower, but not so good in flavour as that variety. A German Apple named Breßling was sent from Mr. Rivers; the fruit had a disagreeable flavour, owing perhaps to the way in which it had been preserved.

FLORAL COMMITTEE.—W. B. Kellock, Esq., in the chair. Two noticeable groups of plants were exhibited at the meeting, and both were from the nursery of Messrs. Veitch & Sons. One was a collection of upwards of fifty hybrid Amaryllises, which in the aggregate had a gorgeous effect, and made more imposing perhaps by the juxtaposition of a collection of well-bloomed Cyclamens. Some of the Amaryllises were named, and first-class certificates were awarded to the following: Phoebe, dazzling flame scarlet, with a buff star, exceedingly vivid and fine; Junius, deep velvety crimson-scarlet and greenish-white star, very rich; Sultan, bright maroon and white, very rich, the petals also having an elegant reflex; Agatha, creamy star, scarlet petals edged with white; and Rev. J. Stainforth, crimson, with white centre and bands, an extra large flower and very fine. There were also many other exceedingly fine varieties. It is almost impossible to adequately describe the vivid colours of these plants; they are intensely rich, and the petals are of good substance. Some of the light varieties are also very chaste. This is probably the finest collection of Amaryllises (or Hippeastrums) that has ever been exhibited. The batch adds another honour to the great Chelsea firm, and the plants will be of immense value to decorators. The collection was highly commended by the Committee. They will be further alluded to, and cultural notes will be given by a successful grower.

The Cyclamens were remarkably healthy and well bloomed, the foliage of the plants being stout and distinctly marbled. The colours were varied, the darker having bright glossy petals, the lighter being mostly shaded and spotted, a few being pure. A vote of thanks was awarded to this collection.

Fransanthes elegans, a "cross between Farboria and Sonchus laciniatus," a standard Grass-like weeping plant, suitable for

table decoration, was exhibited by Mr. Green, Botanical Nursery, Holmesdale Road, Reigate. Mr. James, Castle Nursery, Lower Norwood, exhibited a plant with two blooms of a fine variety of *Dendrobium nobile*. *Peperomia marmorata Stevensii* was sent by Mr. Stevens, gardener to G. Simpson, Esq., Wray Park, Reigate—a small plant with acuminate leaves and nicely marbled foliage.

NOTES AND GLEANINGS.

A SMALL BAND OF HORTICULTURISTS, invited by Sir H. W. Peek, assemble fortnightly at the gardens of Wimbledon House, Surrey, for the purpose of discussing horticultural topics, the reading of essays, &c. This season they have gone on most satisfactorily, and a great number of subjects bearing on horticulture have been warmly discussed. Some of the essays are published, and these gatherings are looked forward to with more than ordinary interest. To Mr. Otterhead, Sir H. Peek's able gardener, great praise is due for the way Sir H. Peek's wishes are carried out, and for the warm and hearty welcome the visitors meet with; and to his exertions are due that within the past few days over forty gardeners have been added to the list of members of the village club and lecture hall. Prior to this the ordinary or working-class members only numbered twenty-two. These new members have issued a circular which has been headed by a subscription of £5 5s. from Sir H. Peek, and others are forthcoming, so that in a little time we hope this village club will have a library of useful standard horticultural works. The honorary members will, we hope, appreciate this effort made by these men, and drop in occasionally. The movement is, we think, a step in the right direction.

— MR. DON is about to leave the service of the ROYAL BOTANIC SOCIETY. The Society will not obtain another Superintendent more able or, in every qualification, his equal for their Superintendent.

— SOME CONTINENTAL HORTICULTURAL EXHIBITIONS of note are announced. An "International" is to be held at Rome from May 6th to 14th, the first of the kind held in the imperial city. A great Exhibition is to be held in Vienna from April 29th to May 4th. The Genoa Exhibition will be held on April 30th, and a great horticultural gathering is to take place at Erfurt from September 9th to 17th.

— MR. SHIRLEY HIBBERD, in a paper read at a recent meeting of the Society of Arts on the "CULTIVATION OF HARDY FRUITS," directed attention in a prominent manner to the irrational mode of pruning generally adopted, and urged the desirability of a free and unrestricted mode of growth to fruit in common with forest trees. The lecturer, in his trenchant manner, alluded to the thickheaded gardeners who go about hacking and slashing, and seemed to take it for granted that trees, as a rule, were pinched and pruned on a system which might be described as preventing fruit trees bearing fruit. While admitting the soundness of the arguments generally it is impossible to ignore the fact that the lecturer was occasionally too sweeping in his surmises. Gardeners, as a rule, must in justice be credited with a considerable amount of knowledge in fruit-production. It is not they who violently restrict and prevent the trees bearing fruit. Many British gardeners are themselves the greatest authorities in practical fruit culture, as their full supplies of fine fruit testify. They know and deplore the pet system of extreme restriction to which many trees have been subjected by amateurs, and are the first to admit the erroneous ideas which have been prevalent as affecting the fruit supply of the nation. Yet, on the other hand, these dwarfed trees (while many have proved profitable) are not always cultivated for profit. It is the pleasure of numerous owners of gardens to cultivate such trees as ornaments or curiosities. The trees are preferred small on the same principle that a great number of small rather than a limited number of huge specimen plants should adorn their greenhouses. On that principle alone the system of dwarfing is justifiable. Like most reformers, the author of the generally useful paper went from one extreme to the other; and it is neither likely nor advisable that a system of no pruning will be uniformly adopted in our gardens. Attention was also directed to a model Peach garden, the trees being trained as espaliers and protected by moveable shelters of boards which can be placed as desired—on the south sides of the trees in spring, to retard the opening of the blossoms until the weather is genial; and on the north sides, to conserve the heat of the sun in summer so as to aid in ripening the fruit and wood. The idea is

worthy of trial; and as it is not patented, a gentleman by the aid of his carpenter and gardener (if the latter is not too "thickheaded") may have crops of fruit on the "wooden wall" system, but—he must prune the trees.

— A SECOND GREAT INTERNATIONAL POTATO SHOW is to be held in the Alexandra Palace on September 28th and 29th, when prizes amounting to upwards of £100 will be offered, the Alexandra Palace Company heading the list by a donation of forty guineas. The last exhibition was a great success—was in fact the finest display of its kind ever held, and the "second edition" will doubtless be as successful as was the first.

— THE adjourned ANNUAL MEETING of the ROYAL HORTICULTURAL SOCIETY to consider the privileges of Fellows for 1876 will be held on Thursday, the 24th, at three o'clock.

— MR. STARK has in the "Journal of the Statistical Society" stated that in the colony of Victoria, Australia, there were in 1874, 9,000,000 VINES UNDER CULTIVATION, producing 105,650 cwt. of Grapes. Most of these were made into wine, an industry which is steadily increasing in the colony. In 1873 there were 88,349 acres of Potatoes, 583 acres of Tobacco, and 16,060 acres were devoted to gardens and orchards.

— THE average production of WINE from French vineyards is estimated at 17,000,000 gallons, and 5,000,000 acres are devoted to the cultivation of the Vine. The annual value of wine, spirits, and liqueurs exported from France is estimated at £16,000,000 sterling; of sparkling wines alone not less than 50,000,000 bottles are exported annually.

ALLAMANDA HENDERSONII.

In the spring of 1873 I planted out in a small border at the back of my stove a young plant of the above. It soon commenced growing, and by the end of September had covered a large portion of the roof, when water was gradually withheld in order to accelerate the ripening of the wood. In February the following year the plant was pruned back and a top-dressing of decayed turf, decayed cow manure, and charcoal was given to the border (the same material being used in planting). In the latter part of May its noble orange blooms began to open, from which time until September hundreds of blooms were picked, when water was again withheld. In February last year the border was again top-dressed and the plant shortened back. About the middle of May the first blooms again opened, and during the four following months it was simply a mass of bloom. During the last Christmas week scores of blooms were picked, although little or no water had been given for three or four months.

Mixed with the brilliant *Vallota purpurea* and the beautiful and chaste *Eucharis amazonica*, with some sprays of Maiden-hair Fern, the combination presents a beautiful appearance. To all who can find room I say—Grow *Allamanda Hendersonii* planted out. I ought to add that during the growing season copious waterings were given and the syringe was freely used.—J. H.

APPLICATION OF MANURE.

THE interesting discussion which took place between Mr. Pearson of Chilwell and the Editors of this Journal on the above subject in the latter part of the year 1869 will be in the recollection of the readers of this Journal. What appeared to me most preposterous was when Mr. Pearson said he had acres of land covered with manure as dry as wind and sun could make it before it was ploughed-in. Since then I have given his system a fair trial, and I have come to the conclusion that he is right, notwithstanding the difference of opinion that may exist between scientific and practical men.

Time and space will not permit to give a detailed account of all my experiments, but I will mention one made in 1874. In March of that year I gave a good dressing of pig and stable manure to a large plot, one half of which dressing was dug-in at once, and the other half was allowed to remain about six weeks on the surface before it was dug-in. The whole plot was planted with Veitch's Autumn Cauliflower. The result from the latter half was so satisfactory that I have decided in favour of Mr. Pearson's practice.

I read from the pages of the Journal the discussion which took place upon the subject before a meeting of the Tunbridge Gardeners' Mutual Improvement Society, when an animated debate ensued, and the prevailing opinion was in favour of

the manure being exposed for some time before it is dug into the ground. I have not written this paper for the purpose of reviving the discussion, but merely to elicit the experience of other practical gardeners.—W. GRAVES.

PARNASSIA PALUSTRIS.

HARDY aquatic or marsh plants have been inquired after, and this "pretty plant with a pretty name" is figured as worthy of notice by those who desire plants of this nature to furnish the damp spots in their gardens. It is popularly known as the Grass of Parnassus, not that it has any resemblance to the Grasses, but the elegance of the plant and its fabled association with Mount Parnassus would seem to be the origin of that poetic appellation.

It is a British plant, found, as its specific name implies, in marshy meadows, and is seldom cultivated, yet is worthy of cultivation. Mr. Robson has written of this plant as being "a low compact-growing plant, in habit resembling some of the Primulas, with a different class of foliage; the flowers, however, are its main points of beauty, and they are very attractive, being white, neatly fringed, erect, and on stalks that enable them to be gathered for nosegay purposes." The plant grows 6 to 9 inches high, and flowers in July. It only needs dibbing in wet boggy soil, and it will grow and flower freely.

USEFUL FRUITS.

SEVERAL profitable letters have recently appeared on the management of hardy fruit trees—their pruning, grafting, and dressing, and for a subject so comprehensive I am surprised that the different writers are so nearly unanimous. A few differences of opinion there have been, but I think they are more apparent than real, and are suggested by local circumstances. I mean, that had the writers all argued from the same orchard they would have been very much alike in their opinions. That I think demonstrates the writers to be practical men, and gives great value to their communications.

So far as the discussion has gone I perceive the following points are agreed to:—First, not to hurriedly destroy an old tree before its successor is established; second, not to prune an old tree, especially if solitary, but leave that operation to Nature; third, not to hesitate to graft a stock provided it is healthy; fourth, not to fear the cutting-down of a tree if its stem is clean and healthy, while the upper parts are knotty and gnarled, the sap vessels choked, so that it may produce new parts; and fifth, to keep the trees, particularly the young wood and fruit-bearing spurs, clear of lichens.

Those conditions are pretty well agreed upon, and I believe them to be sound. As to the mode of carrying them out, each gardener must adopt that which is most suitable to his circumstances.

All that has been said is useful and worth remembering, but something—in fact, a great deal, more is needed to render the discussion completely satisfactory. There are in my opinion two very important matters relative to this subject which as yet have not been alluded to. I should regret for these to be overlooked, and as I take myself to be a representative of hundreds of others, I ask that consideration be given to these two main points—namely, what form of tree is the most useful? and what kinds of, say Apples, Pears, and Plums are the most

profitable for certain soils and districts?

I am convinced that valuable information will result from a discussion of these questions. The demands for fruit are immense, and it is only by the aid of the foreign markets that these demands can be met. Cannot more fruit be grown at home with advantage to the consumer and with profit to the producer? Will not fruit culture realise a return as great or greater than devoting all the land to agricultural purposes? These are important questions. Dwellers in cities are apt to envy the position of the rural population with their advantages of fruit-production, but I think it is very near the fact that fruit is cheaper in cities than in country towns and villages. This ought not to be, for the resources of the country are sufficient to meet the aggregate demand for fruit if those resources are turned to account and based on the experience that cultivators are now able to adduce on this question.

The two main points which I have propounded may possibly have been discussed before, but if so, a vast amount of knowledge has been gained since then, and if that knowledge could be condensed and brought down to the present time the advantages could not fail to be great.

It would be further useful to have some data as guidance aiding to a selection of kinds, but this cannot be too simple, for many conditions would only perplex. Soil might be named as heavy, light, or medium, with an allusion to subsoil; high or lowness of site, and light or heavy rainfall, it would be useful to know; and as to

districts a specification of north, south, or midlands will be sufficient for all practical purposes.

I have long thought of mentioning this matter, but I scarcely knew when and where to do it, but the letters which have recently appeared convince me that now is the time, and "our Journal" the place, to bring the matter forward. If these suggestions are by the "powers that be" thought worthy of mention, I will in a future letter give an example of what I mean, by naming the kinds of fruit that I have found the best and most useful in my midland-counties district.—AMATEUR ORCHARDIST.

Fig. 81.—*PARNASSIA PALUSTRIS*.

ROYAL HORTICULTURAL SOCIETY.—The Earl of Mount Edgcombe and G. T. Clarke, Esq. were elected, at a special meeting of the Council held after the adjourned Annual General

Meeting on the 10th inst., to fill the vacancies caused by the resignation of Admiral Hornby and Mr. A. Grote, F.L.S.

NEW FRENCH ROSES.

THE time has passed, I think, when one used to scan with intense interest the lists of forthcoming French Roses. Is it that the scanning has palled upon one, and that which once caused excitement has ceased to have its effect? or is it that we have been so often deluded by the high-sounding epithets—the “magnifique,” “superbe,” “varieté extra,” &c., which have turned out so fallacious that we cease any longer to look for the one or two grains of gold in the vast quantity of sand? or is it that the English raisers, Messrs. Turner, Paul, Cranston, &c., are giving us such good flowers that we do not care to look so far afield? Perhaps all these causes have combined to work out what, as far as I am personally concerned, is a fact. The test, too, that we used to apply—namely, the character of the raisers, does not now seem to hold good, as indifferent if not worthless flowers flood us on all sides and from all growers. However, it may not be uninteresting just to see what they promise to us for 1876. I find from M. Charles Verdier's list that there are thirteen Teas, one Noisette, one Bourbon, and forty-four Hybrid Perpetuals, besides some four or five others of other classes, such as Perpetual, Noisette, Hybrid Provence, &c.

In Teas the largest number come from the widow Ducher, who gives us five, Pernet three, Levêl three, Guillot one, and Oger one. The Noisette is from Levêl, and the Bourbon from Schwartz, successor of old Guillot.

In Hybrid Perpetuals Mons. Eugène Verdier heads the list with (oh, fortunate man!) twelve new varieties; Lacharme, to whom we owe some of our very best Roses, has four; Levêl two, Souperet at Notting two, Schwartz three, Oger two, Liabaud three, Moreau Robert three, H. Jamain one, Fontaine two, Vignerot three, Ledebaux two, Margottin fils one, Gonod one, Brasseur one, Lapland jeune one, Eugène Genoux one. The last three names are quite new to me, would that it might be the omen of some new break in the interminable list of crimson, rose, tender rose, &c., with which we are inundated. Where amidst all these shall we find the novelties we desire—the flowers that are to create a sensation and to remain *en permanence* in our lists? Echo answers, Where? There is good old honest Lacharme, whom I regard as the king of French Rose-growers, will he not have something in his four new Roses for us? Jean Souperet sounds tempting—large flowers, imbricated, velvety purple; so does Henri Bennett—fiery red and lively carmine. But it is useless guessing, and we must only look forward for our coming shows. But one cannot help thinking that the palmy days for the French Rose-growers are over when the English nurserymen bought everything, propagated largely, and year after year found that they had wasted their stocks, their money, and time. They now, I believe, act more cautiously; but even now they have to lament their precipitancy. Do I not know of one of our most eminent Rose-growers who two years ago bought an English-raised Rose of great promise, paying some £60 for it, and after propagating it to a large extent, finding that it was not up to the mark and would do him no credit if he sent it out, ruthlessly condemned it all to be rooted up and burnt? It was, as he said, a bitter pill to swallow, but better to make a gulp at it than to continually have the taste in one's mouth as customer after customer denounced it.

We have now fairly entered on the competition for new Roses with the French raisers, and I think we may regard the issue with confidence. There is one Rose yet to be sent out which we all saw last season, Mr. Turner's Oxonian, which promises to be one of the most beautifully shaped and exquisite Roses yet raised.—D., Deal.

PEACH-BLOW POTATO.

I HAVE grown the Peach-blow four years. I thought much of it, as did all who ate it, until this year. It now has a large black core, and it is one of the worst affected by the disease. Another objection is that the tubers are too large for a gentleman's table. It is a heavy cropper, but I think its good qualities are outweighed by its bad habits, so shall discard it this year. “J., Lincoln,” speaks of Peach-blow as ripening early. With me it was ready to lift just before Flourball. I strongly suspect Flourball is of American origin, for I had it from America (brought by a friend) the year after it was sent

out by Messrs. Sutton & Sons under another name, and I have had it badly affected with curl for two years.—LINCOLNSHIRE WOLD.

VINCA ROSEA RAISED FROM SEED.

UNDER the above name is generally known a popular old stove plant which is usually raised from cuttings. The correct name of the plant is, I believe, *Catharanthus roseus*, and the readiest and best mode of increase is by seeds. Vines and *Catharanthus* both belong to the same natural order, Apocynaceae, but the former are hardy and the latter are tender plants.

The plant noticed was introduced from the East Indies about 160 years ago, and straggling plants are frequently seen in stoves and vinerias. It is a stove plant, requiring heat, light, and moisture in the summer months, and a winter temperature of 50°. When well grown this is an attractive summer-flowering plant, and may be trained to any desired form. Fine plants of it have frequently figured at exhibitions. By frequently pinching the shoots a dense bush habit is insured. Good plants may be raised from cuttings, but neither the foliage nor flowers are so fine as on plants raised from seed.

Seed sown now, and the seedlings grown in heat, will make splendid flowering specimens during the summer. I have, with the aid of sufficient top and bottom heat, had plants more than 8 feet through the same season, dense and globular, and masses of bloom. They were shifted on as required, blooming them in 8-inch pots. In their early stages a compost of peat, loam, and leaf mould is suitable, but after attaining a good size they should be potted in rich loam and manure. They require an abundance of heat, light, and water, and then few plants will grow more freely. They are effective conservatory plants during the early autumn months.

After flowering and resting they may be cut down similarly to *Pelargoniums*; but the flowers on such plants are not so fine or the foliage so exuberant as on plants raised from seed annually. The white variety is also highly worthy of culture. By a system of resting and pinching these plants may be had in bloom at any season, summer or winter.—T. B.

PEACH PRUNING.

PEACH pruning is now in hand, and I strongly recommend a free use of the knife. I once heard a discussion of the treatment of shoots studded with blossom buds and with only a terminal wood bud. The decision was to leave them unpruned, because the removal of the terminal wood bud would cause the blossom buds to fall, which they undoubtedly would do, but in any case the fruit would prove small and poor-flavoured. Such wood should therefore always be cut entirely away. Do not mind if the adoption of this rule leads to an apparently undue amount of severity in pruning; never rest content with weakly trees and undersized fruit, or with quantity at the expense of quality.

Every season one meets with trees of weakly growth and sickly condition overlaid with fruit, small almost without an exception, and one knows from dear-bought experience how hopeless of improvement is the future of such trees unless they happen to come under a common-sense mode of treatment. By this term I mean a system of culture based upon the evident requirements of the trees. We never can upset the balance of Nature with impunity.

Strong mature wood thinly disposed bears large fruit if it be not overcrowded. It puts forth other shoots often more vigorous than itself. It does not shed its blossom, owing to its ample store of nourishment, the prompt and ready action of its full flow of sap answering every requirement of blossom, fruit, foliage, and wood growth; and it is less liable to the attacks of noxious blight or insects than the tree of weakly growth—weakly either from premature or heavy cropping, faulty pruning, insufficient nutriment, neglect, or mismanagement of some kind or other. Evidently there is a want of balance in such trees. We cannot induce small wood to bear large fruit, nor ought we to expect anything but future deterioration if it has been suffered to bring an abundant crop to maturity.

Here are a few leading points of common-sense culture in reclaiming a mismanaged tree. Cut-out every particle of weakly growth; cleanse the wood from every substance likely to prove hurtful to it; see that the roots are in a rich, wholesome, well-drained soil; cherish and protect the foliage as you

would the blossom. Remember that healthy foliage points to vigorous wood growth, and that aphides and red spider cannot stand clean water, meet therefore their attacks with the sponge and syringe. Do this promptly, watching for invaders, and if possible dislodge the skirmishers, and the attacks of every one of your enemies will fail. Lastly thin-out the fruit, determine to produce the best that can be had in size and quality; and although you may not attain to the highest success, yet the very fact of striving to do so will certainly lead to results of more than ordinary excellence.—EDWARD LUCKHURST.

ROSES FROM CUTTINGS—PRUNING—REPOTTING.

In answer to the questions of "ST. EDMUND," I entirely disapprove of this mode of propagating Roses, and if he thinks he will have good blooms on them this year he will be much disappointed. It takes years to form a good Rose tree from a cutting.

With regard to pruning, I strongly advise (and I fancy my friend Mr. Peach will concur with me) him not to prune them at all. Let them follow their own "sweet will" and grow unchecked. The first object is to root them, and that will take a long time.

With regard to "ST. EDMUND'S" second query as to repotting, I should recommend him about the beginning of March to repot them in larger pots, and if he can manage it to make a hotbed and plunge the pots in it. In the summer he can take them out and plant them in the open, and next year he can cut them hard, and perhaps in 1878 they may produce good blooms, but I doubt it. I never knew a good Rose shown from a cutting yet, but of course I may be mistaken.

Mr. William Paul is the only nurseryman with whom I am acquainted who grows what are called "own-root Roses."

With regard to this mode of culture I will conclude with a story, told I think by Mr. Winwood Reade, about a certain farmer who never went to bed sober, his particular liquor being brandy and water. This worthy man once paid a visit to a relative in "Zomerset," where the only available liquor was "zider." The farmer feeling that his health—nay, perhaps his life—depended upon his making no exception this night to the rule which he had kept for so many years, set to work to bring about the desired result with "zider," but after he had finished his twentieth tumbler he found he was no nearer the haven than he was when he commenced, and so he sighed as he filled up his next tumbler and said, "This is very weary, weary work," and so I am afraid "ST. EDMUND" will find propagating Roses from cuttings.—JOHN B. M. CAMM.

AZALEAS FOR AUTUMN AND WINTER FLOWERING.

THERE are few flowering plants more effective at any season than Azaleas; but they are perhaps more striking and most appreciated from October till the end of the year, when flowering plants are at their scarcest. To bloom them at this season requires some little peculiarity of treatment and a selection of sorts that are best adapted for being forced thus early. It is necessary that they be introduced into a brisk heat and moist atmosphere early in February to make their growth and set their buds early; for unless this be taken as a first, and a season of rest allowed as a second step, the process of forcing them into bloom will not be satisfactory. It is also a favourable condition that the plants be under rather than overpotted, for if the pot is not well filled with roots the tendency of the growth is to be long, and continued later in the season than is desirable; while, on the other hand, a pot well filled with roots produces a short stubby growth, which stops growing sooner, and, as a consequence, sets its buds earlier.

The following are the best that I have tried for getting into bloom so early as October: President Van den Hecke, white, striped and spattered with red. Not by any means a first-rate flower, but the earliest we have tried.

Charles Leiretins.—This is a comparatively new and rare variety. Bright carmine-red; semi-double, very easily brought into bloom early.

Iveryana.—White, striped with crimson. One of the earliest and most free-blooming of all the early varieties. Forced thus early, all the blooms come almost entirely white and without the usual crimson marking.

Beauty of Clapham.—Rich rose-pink.

François Devots.—Clear crimson, semi-double. This is not so early as the foregoing, but can be had in full flower in November; when in contrast with the light varieties it is very effective.

Borsig.—This is a white variety that we know to be a good early one; but not yet having a stock in proper condition for autumn blooming, we cannot speak of it from experience.

These, bloomed at a season when really effective flowering table plants are scarce, are most effective and useful. For room-decoration they are invaluable, for when put into a drawing-room where something more than half the blooms are expended, every one opens freely, and they stand such work longer than most flowering plants.—D. THOMSON.—(*The Gardener*.)

AURICULAS.

LIKE your correspondent at page 106, I am aware of Mr. George Glenn's notes upon Page's Champion, and had read them and tested them in practice before I ever wrote about Auriculas. Those strictures will apply to Champion when he is "out of character." I have seen all those faults in him, but I was thinking of him at his best. The Auricula is yet an uncertain sportive flower, and a perfect one that is constantly perfect has yet to be raised.

Champion is not an easy sort to obtain in its best form, and with regard to Taylor's Glory I have never seen or bloomed it without its wavy paste. But the other great flowers have also their weak points or uncertainties; and while Champion and Glory stand as they do in the best few of their respective classes, the time has hardly come yet to say to an inquirer, "You need not trouble yourself about Champion and Glory."

And, again, I am hardly ready to think with "G. S." that in the scarcity of the Auricula "fancy throws over them a halo which conceals defects" once visible enough when the flower was common. Scarcity is not a desirable point, and it is no property in a good florist's flower. It is nothing in favour of a weak flower to say, "Well, but it is scarce." The scarcer a bad flower is the better. Faults, so far from being now lost sight of in a love-mist of fancy, are all the more keenly seen and felt. In the Tulip and Carnation very great improvements have been obtained. The Auricula is yet a little behind; while far in the rear, friendless and forlorn, last straggler of them all, lags the yellow Picotee.

It would not be difficult to name some inferior green and white-edged Auriculas that would be found as scarce as Champion and Glory; but among those who know the flower, their simple scarcity creates no pressure of demand for them and covers no fault. They quietly drop out of sight. So also will it be in time and turn with Champion and Glory when we have obtained flowers more constant than beat them at their best.—F. D. HORNER, *Kirkby Malzeard, Ripon*.

As "our Journal" is a pleasant exercising ground for our hobbies, will you permit me to mount mine, and take a short canter? In answer to your correspondent "G. S." I desire to express a hope that "ALFRED" is too enthusiastic a lover of Auriculas to be able to take his advice and "live very comfortably without having either Page's Champion or Taylor's Glory." It is, no doubt, kind of "G. S." to comfort "ALFRED" when sighing after the unattainable. But when he proceeds to depreciate those two exquisite varieties, loyalty to my floral queen forbids my silence and prompts the suggestion, How very sour are those Grapes that are hanging out of reach!

I do not pin my faith on any saying of Mr. Glenn thirty years ago, in contradistinction to Mr. Horner and many living authorities who, I know, think most highly of these varieties. I consider Glenn's account of Champion thoroughly incorrect. So far from its "texture being uncertain, the paste thin, and the pipe generally wanting flatness," I have always found it quite the reverse. It is a flower of great substance and lasting powers; the paste is far from being thin; and the flatness of the pipe is one of its chief beauties. I grant that if the flower truss at any stage of its development is touched by frost, then indeed "the paste cracks, the petals divide, and the pipe is much crumpled;" but this is the fault of the florist, not of the flower. As regards the ground colour in Taylor's Glory making through the edge, over-stimulating food is often the cause; and I know no Auricula which may not be spoiled in like manner.

In my opinion "ALFRED" would do well to adopt Mr. Horner's

estimate, and not "live very comfortably" until he possesses and grows well *Champion* and *Glory*.—FREDERICK TYMONS, *Clk.*

CORYANTHES SPECIOSA.

This belongs to a genus of which the flowers are of a very singular character, some of the species being also remark-

able for their handsome appearance. One thing very much against them is that the flowers only remain in beauty two or three days. At the same time, wherever a collection of Orchids is grown some of the species of this genus should find a place.

Their culture is not difficult. Like most Orchids they require a season of rest after the growth is completed. The

Fig. 82.—CORYANTHES SPECIOSA.

house should be cooler at the resting period, and the roots ought not to be watered until the compost is dry. During growth the plants require good supplies of water, and the roots must not suffer at that time. The pots should be filled two-thirds of their depth with potsherds, and some clean sphagnum

be placed over the crocks. The best compost is very fibry turfy peat and sphagnum in equal parts. They also succeed well in baskets, and will also grow on blocks of wood.

C. speciosa is a native of Brazil, and requires to be grown in the warm house, at least when making its growth. The leaves

must be kept quite clean by occasionally sponging them with tepid water.

THE ARRANGEMENTS OF COLOURS

IN THE BEDS OF THE LONDON PARKS AND GARDENS.—No. 6.

LARGE masses of black or dark brown are always productive of more effect than large masses of white or grey. Black and

| 3. <i>Alternanthera paronychioides</i> ma- | |

white in masses should be sparingly introduced everywhere where the end to be attained is gaiety, variety, and beauty. The good colourist has not only to study harmony of combinations, but suitableness and local fitness, and he will require to vary his scale of colours in depth and tone. For some aspects,

| 3. <i>Lobelia Blue Bonnet</i> , a rich blue | |

such as near the house or building, he must use cold and soft colours; for distant effect, warm, deep, and rich colours

are necessary. It should be remembered that if any of the primary colours have a mixture or shade of another primary it loses its purity and becomes, in a degree, secondary. The secondary which is complementary to it must contain more of the remaining primary. Thus, if red tends towards scarlet, which is an orange red (red with yellow in it), the green, to be truly complementary, should incline towards the remaining primary blue, and be a blue-green. When red, on the contrary, tends towards crimson (red with a blue in it), then the complementary green should incline towards yellow, and be a yellow-green, and the like rule holds good as to other primaries.

In the harmonies of tertiary hues, as well as of tints and hues, some of the most refined and beautiful arrangements will be found. Thus, primrose, which is a tint of yellow, is in harmony with lilac, which is a tint of purple; while straw colour, which is a tint of orange slightly neutralised, is contrasted with a negative blue tint. These intermediate shades and tints, when nicely arranged, are very satisfactory to the eye, and when harmony is attained from their arrangements the pleasure is greater than from those of the simpler and more obvious kinds of contrasts.

The examples submitted require only a few varieties of plants, and their simple flowing arrangement presents an agreeable change to the more elaborate modes of planting

which have previously been given as suitable for circular beds. I will next consider how oval-shaped beds may be effectively planted.—N. COLE, *Kensington*.

GLASS COPING AND FRUIT CROP FOR 1875.

No. 2.

WHILE admitting that glass coping afforded but little assistance last spring towards the fruit crop, I am equally satisfied that in many, and perhaps in most seasons, it would be of the very greatest value—for instance, a cold, wet, boisterous spring with sharp frosts alternately, would ruin any prospect without the protection of coping and its appendage a screen.

The screen, I am persuaded, is no less valuable than the coping in inclement and windy weather. The south-westerly winds are the winds that prevail just at the critical time of flowering. Now with these winds the coping in itself would cut a poor figure to save the crop. I look on these wet cutting winds to be far more destructive than the hard dry frosts. The wind drives home to the very flower, carrying death to the tender herald of our hopes—a crop. That dry flowers will stand harmless a few degrees of frost is well known, hence coping is so strongly recommended. Coping alone with “south-westerly” avails but little, but a good screen in conjunction will make all safe and comfortable. When I advocate coping I include its

necessary adjunct—a screen, for if anyone rests his hope on coping alone, that hope will be lost as sure as the crop. Expectations there will be, I am well assured, under circumstances similar to those of last spring. May they be many, and then, as I have before said, under liberal treatment a reward may be expected.

If we judge from your correspondent Mr. Taylor of Long-leat, we have not well-ripened wood to support the crop this spring, though this is not my case. He comes to a perfect conclusion in saying the crop will be void or almost so. Now I put the question to those who believe that glass coping must produce a crop, if it is reasonable for trees of Mr. Taylor's character to do so if coping were placed over them? The answer must be—Decidedly not. And this is just equivalent to having the trees roasted to ripeness by the end of August. Will coping remodel the puny imperfect bud before it opens? Certainly not. A failure in both instances is sure; but put a coping over a healthy crop of buds shaded with a screen, we can do much. But copings alone cannot insure a crop, as is expected by not a few. Of this we have been convinced by the failures in unheated glass houses.

But why do I dwell so long on the uncertainty of crops under coping? My success the last season was seen by many. It seems my employer never had anything in the garden that gave him so much pleasure. The crop was immense; many were brought to see it; many of them doubtless will have glass coping on the strength of what they have seen, being—(bear in mind, these trees had never produced a crop since being planted seven years ago)—well assured after the coping is up that nothing is required but to wait and then gather the fruit. Then woe be to that gardener the season the fruit is wanting.

—JOHN TAYLOR, *Hardwick Grange.*

GRAFTING AND INARCHING VINES.

FREQUENTLY are instructions as to changing the varieties of Vines solicited, and as this is a favourable season to mention the matter I may, perhaps, not unprofitably detail my practices. No plant or tree that I am acquainted with may be operated on with a greater certainty of success than the Vine. It may be grafted or inarched almost at any period when the sap is moving, and by any mode that is applicable to other plants or trees. It may be whip-grafted, crown-grafted, or side-grafted in spring, and may be inarched in spring on the old wood, or in summer on the growing shoots.

Where a Vine in a pot is provided all that is necessary is to shave off a portion of its bark and wood and a corresponding portion off the stock and fit the former to the latter neatly, tying closely but not tightly, and surrounding the part with moss. The root of the pot Vine will afford support until the union is complete, when it can be gradually severed, leaving the foster parent eventually to support the new branch and future Vine. The inarching is best done when the stock has grown an inch or two and when the young cane to be attached is just swelling its buds. The young shoots of each may be also brought together when in a growing state and the union is speedy, but the operation must then be delicately and dexterously performed, and care must be taken that the ligatures are not too tightly bound. This other plan is perhaps the most to be recommended for ordinary practitioners.

But Vines may require to be grafted or inarched, and when no young canes in pots are provided, and recourse must then be had to bottles of water. If one end of the scion is inserted in water that will answer all the purpose of roots, for the water will support the graft until it has united to the stem to which it is affixed: that is the simplest and the best of all modes of grafting the Vine.

The grafts should be 18 inches or more in length, of stout, well-ripened, fruiting wood. Starting at two or three buds from the top of each a good slice nearly to the pith and also 6 inches long should be taken from the graft, another similar slice being cut from the stock, and the two cuts bound neatly together. There will thus be 6 inches to form the union, 6 inches above it for growth, the portion of the graft below the slice to be inserted in a suspended bottle of water. Ordinary wine or pickle bottles are suitable, and they should be filled with water, adding also a few lumps of charcoal. Smaller bottles are not suitable, needing too frequent attention in replenishing the wasting water.

These bottles should remain for several weeks, indeed until the graft has grown nearly to the top of the house. The ligatures may also remain a long time. The grafts will probably

take root in the bottles, but no injury whatever follows after the graft has become thoroughly united to the stock. These grafts will perfect fruiting canes the first season in all respects as good as if they were regular growths from the Vine. Indeed if they are stopped beyond the bunch which each will show, if the wood is strong and good, these bunches will be in all respects perfect bunches; thus by this means a bunch if desired may be secured on any given part of the Vine: that is sufficient proof of the efficacy of the plan. It is so simple and certain that none need hesitate to adopt it who desire to change the varieties of their Grapes without planting new Vines. I have tried the plan thoroughly, and seldom if ever met with a failure.

I first read of the plan in the Journal, and went to see the place which was described on page 77, vol. xxiv. I found more than a hundred Vines so grafted, many of the grafts being the same season 20 feet in length, and the stocks on which they were grafted bearing a good crop of fruit. The gardener had received his instructions from Mr. Knight of Floors Castle. Some of the grafts were attached to the old stems (four or five-years-old wood) of the Vines, but the finest rods were those worked on the shoots of the previous year, and of the same size and age as the scions.

The great point is to have grafts of well-ripened wood and make the slices both long and deep. A little moss may be tied round them, but that is not really necessary, provided the matting bandages are well applied. The operation may be performed any time in the spring, just when the Vines are being started into growth, and the bottles should be kept filled with water until July or longer, and the ligatures may remain for some time after that.—W. B. S.

SOIL FOR RHODODENDRONS.

MR attention has been called to the fact that the paper on "Soil for Rhododendrons" on page 84, contains an apparent contradiction in the statement that the soil must not contain lime, and yet that they answer well in marl, which all the authorities assert contains a certain quantity of carbonate of lime, yet differ widely as to the correct per-centage which any soil must contain to entitle it to rank as marl, some being content to accept a minimum of 5 per cent., with a maximum of 20, while others are satisfied with nothing under 15 per cent., and actually admit a maximum of 75 per cent. If we are to accept either dictum, then I must withdraw my assertion, for the soil which I have termed marl in perfect good faith has been tested with an acid, and certainly contains no lime, but consists almost entirely of silica in very minute particles, and alumina, the silica predominating very considerably. It is very light in colour, almost white.

The common acceptance of the term marl is, I apprehend, somewhat vague, and I should much like to know if the rule regarding the presence of lime is an inflexible one. Apart from this matter, the importance of my account of the hardness and adaptability of the Rhododendron must be quite patent to all. So important do I consider it, that I strongly reiterate the fact that Rhododendrons will flourish in full vigour in any soil save that which contains lime. Thus far much practical experience enables me to speak positively; but is it not questionable whether all calcareous matter is fatal or even hurtful to the roots of Rhododendrons? To put the matter upon a broader basis, Has anyone proved to demonstration that limestone of every description is really so pernicious a substance as is imagined?

Popular ideas have such great weight that they are not easily set aside, however erroneous they may prove. The supposed necessity of peat for Rhododendrons is an instance of this. It was only some four years ago that a gardener of considerable experience in many things strongly advised me not to risk Rhododendrons in any other soil, insisting upon it that peat was an indispensable necessity. A little later on another visitor was lamenting that he could not plant Rhododendrons owing to the scarcity of peat in the vicinity of a new garden which he was making, and I have a keen remembrance of the evident satisfaction with which he became convinced that he could plant this magnificent shrub in all parts of his garden, and that a bed of Rhododendrons need not be so expensive a luxury as was supposed.—EDWARD LUCKHURST.

THE notes which appeared in your issue of February 3rd I read with much interest. I agree, as a rule, with our friend Mr. Luckhurst, but I confess I cannot this time. He says

Rhododendrons will grow in nearly any kind of soil. Such a statement I think is apt to mislead. It is true they will live in loam, but you do not often meet with loam that is suitable. One of our great nurserymen says they can be grown without peat soil. Well, we had some from there, and what kind of soil had they been grown in? Why, that beautiful sound yellow loam that makes a gardener's teeth water when he meets with it; but I do not hesitate to say they will grow much better with a little peat about them.

In the spring of 1860 I moved a lot of Rhododendrons that had been planted in the common soil of the place, such poor plants that I was sorry for them. I thought I would try if I could not put a better face on them, so I gave them three or four barrowloads of peat soil. In a year or two the effect was wonderful; they seemed to revel in it. In the spring of 1872 I had again to move the same plants, but what a change! Some of them would be from 3 to 5 yards across, with every bit of the peat soil full of roots; you could do anything with them. They are now in full vigour again.

About the year 1864 I planted some in front of a plantation in strong soil approaching clay. I should think something like what our friend Mr. Luckhurst talks about, but grow they cannot—they seem unable to fasten hold of the ground. I say again, Give Rhododendrons some peat soil if possible.—J. B.

FURTHER REMARKS ON OLD APPLE TREES.

WHETHER it be a fitting source of regret or the contrary, it is pretty evident from what has been said on the subject that the respect paid to venerable old Oaks, Beeches, Yews, and even Thorns, does not extend to Apple trees, as no one seems to wish to prolong their lifetime after they cease to be useful; only there remains the knotty point to settle, When is a tree old and no longer profitable? This problem, like many others, depends on the opinion of those who are directly interested in the trees. Your correspondent "AN OLD GARDENER," page 91, justly complains of the Hawthornden Apple canker with him, and consequently the tree will have all the appearance of age except in size at an early period of its existence, a fact very common with that kind everywhere that I have seen it. Although in some situations it is said to grow kindly, I have never seen it do so for more than a dozen years or so. I believe it is but little planted now-a-days, there being plenty of kinds with all the qualities of the Hawthornden, and much better constitution. The New Hawthornden is very likely to supplant its old namesake, but substitutes for the Ribston Pippin are not so plentiful, which, like the Hawthornden, refuses to thrive in many places, and sooner or later becomes cankered, diseased, and unsightly, so that the term "old tree" may very often be applied to the Ribstons that exist in a mixed orchard where the other trees are hardly at their best; but the experienced orchard manager generally knows these peculiarities, and only plants those kinds which thrive in his locality.

Speaking, however, of old Apple trees and how to treat them, one writer, "RADICAL CONSERVATIVE," recommends cutting them down and re-grafting them, and suggests that—as the tree I referred to on page 51, died or nearly so at the end of four years—if I had cut it down to three or four heads instead of about forty, the tree would have succeeded. As I said before, I was not at all surprised at the tree dying when it did, but if I had cut it down as severely as he speaks of I should have expected it to have died one if not two years sooner than it did, besides which it would have been inconvenient inserting some twenty or more kinds of Apples on three or four crowns. That plan was antiquated even in the days of Abercromby, who complains of the grafts being liable to be blown out even after four or five years' growth, consequently it is safer and better to cut the trees into a great number of heads; moreover I may say that experienced men never cut down old or diseased trees for the purpose of grafting them, but healthy large trees are frequently done so, and answer very well. I am still of opinion that there are only two courses available for treating old trees, the one being to let them alone, the other to grub them up. No middle course is satisfactory. Pruning if severe may produce a larger amount of foliage the year it is done, and the operator may fancy that he has improved his trees, but wait three or four years and mark the result, the fact being that old trees cannot endure the ordeal of severe amputations. Younger trees do better, and may be operated on with advantage, either in the way of pruning or of cutting down and re-grafting.

A correspondent has alluded to the fact of solons placed on an old tree producing fruit sooner than young stocks are

likely to do so. This, no doubt, is the case, but I expect a middle-aged tree cut down would produce fruit as soon as an old one, or if not, it would continue to do so longer; nevertheless, it is very good practice now and then to cut down trees of inferior kinds to graft with better sorts. Some years ago, having a quantity of seedling Crab stocks by me, I selected upwards of twenty of the most promising, and took grafts from them which I worked on an Apple tree that was headed-down to some forty or fifty heads, the remainder being worked with a popular kind having only a local name. These seedlings all fruited at the end of two or three years. This tree has since done pretty well, but it was not too old a one, it being the old and diseased trees that it is not advisable to meddle with. Perhaps, however, a good coating of manure might be of service, and the folding and feeding of sheep is assuredly beneficial to orchards. A coating of dung, however, is no doubt the easiest application that can be given.

Although I have elsewhere stated that many Apple trees look old and are much past their best at the age of thirty or forty years, there are others that continue to bear fruit scores of years after that time. In a park here are the remains of an orchard, and very old people inform me that the trees were old but in a good bearing state at the end of the last century. These venerable trees, now reduced to five that are alive, have been noble specimens in their day, and I had the curiosity to measure them to-day and find in height they all exceed 30 feet, two of them being nearly 40 feet. They appear to have had stems 6 feet high, clear and straight, but as most of the lower limbs have been blown off or are gone, the stems are in reality much higher, and there are but few of the branches lower than from 15 to 18 feet from the ground, and the girth of the stems at places where they are quite smooth and about 4 or 5 feet up is from 5 feet to 6 feet 7 inches. These old trees produce fair crops of fruit in favourable seasons. I dare say one of them had at least ten bushels upon it the past season if they could have been gathered, but they require a ladder so long that it is very difficult to reach them, and as fruit was plentiful only a few were gathered.

Now there is every reason to believe that these trees are 150 years old, and from tolerable good sources I can learn that during the present century at least they have had no pruning of any kind beyond what nature provides for all old trees—viz., a limb now and then dropping off. The growth of these old patriarchs is mostly limited to the formation of spurs; but I managed one year to obtain a few grafts, which have taken and look promising, and it will be well to note hereafter whether their progeny possess so robust a constitution as they have shown; but it is only fair to bear in mind that these five trees are the only trees remaining alive on ground that was once an orchard of several acres, and that near them are trees of other kinds risen-up since they themselves had arrived at maturity, and now large enough to shelter them in a certain degree. Added to these advantages I may say that the ground is good. Still for all that it is seldom that trees of such an age are met with, and most likely they would not have been in existence now had they not been treated as I have recommended as being one of the only courses applicable to old trees—namely, to let them alone.—J. ROBSON.

NOVELTIES IN THE ROYAL GARDENS, KEW.

HAVING figured in a recent issue one of the Euphorbias supposed to yield the gum euphorbium of commerce, we now draw attention to *E. resinifera*, of which there are two plants in the Succulent house. This is a native of Morocco, and is defined in the "Pharmacographia"—an exhaustive work, of which the late Daniel Hanbury was one of the authors—as the true plant; and as no mention is made of the other species we may suppose them to be disallowed. In another work, however, it is said that "in all countries where they grow some of them have been, or are, employed medicinally." The plant yielding euphorbium was first described by an English merchant named Jackson, and from the figures he published was doubtfully referred to *E. canariensis*, which abounds on arid rocks in the Canaries. In 1849 the existence of a difference was pointed out, and subsequently the correct plant was figured and established by Berg as *E. resinifera*. Of this specimens were sent to Kew a few years ago, and are now flourishing plants. They are readily distinguished by the glaucous blue appearance of the young growths, and the stems are four-angled, which in this is perhaps a constant character, as it is so described and no deviation as yet appeared. *E. canariensis*,

on the contrary, is five-angled, though branches often commence growth with four, afterwards assuming a fifth, and the colour of the young stems is distinctly inclined to brown. This species is pretty well known, and as the other is similar in habit we need not enter into minute description.

Euphorbia is a drug of very ancient use. Its collection was described by Dioscorides and Pliny; the name, according to the latter writer, being given in honour of Euphorbus, physician to Juba II., King of Mauritania, who died about A.D. 18. It is obtained by making incisions in the green branches, allowing the milky juice to flow, which having hardened by exposure to the air is ready for collection. The collector is obliged to tie a cloth over his mouth and nose to prevent the entrance of the irritating dust. It has a place in all the early pharmacopias, but as a remedy it is now obsolete, and is said to be in some demand as an ingredient of a paint for the protection of ships' bottoms.

To this we may add a few remarks on cultivation, answering equally well for others of similar succulent habit. As might be supposed, they prefer a sunny position. The winter temperature should be from 40° to 45° as a minimum, while in summer, when fire heat is not required, the house with sun heat may rise to what it will, supposing there be a moderate amount of ventilation. It is a good practice not to close the house entirely at night. Being kept dry when at rest it is important to observe when there is inclination to grow, so as to give the required amount of moisture, otherwise the growth may be stunted, as is sometimes the case with Cacti: so treated they get into a weak unhealthy state, and may remain in that condition for a length of time, or even die. Generally speaking Euphorbias and Cacti, as well as most other plants having a dry season of rest, require during their activity a considerable amount of moisture, as it were to balance and prepare for the time of drought.

In potting it is important to insure good and lasting drainage. The compost should consist chiefly of loam, with a good part of broken bricks, throwing in all the chips and dust, and if sufficient is used no sand will be required. The larger pieces may be used for fixing the stems, if they are not already firm, on the roots, which of course they should be if not shaken out. This is usually the best method when support is necessary. The only method of propagation is by means of cuttings, except when seeds are imported. They grow so very easily that no instructions are required. Cuttings may be taken off whenever sufficiently firm, and if possible should be removed close to the parent stem where there is usually a contraction, so as to have as small a cut surface as possible. Unlike Cacti, they are not benefited by being laid in the sun, and will not throw out roots in the air. As soon as the end is dry each cutting should be placed in a small pot as will hold it, and be fixed in with bits of brick, using the same compost as for potting. They root best on a shelf near the glass. At the present time some Euphorbias are inclined to grow, and those that have started must have water occasionally, but no encouragement should be given till the days are longer with more sun, when syringing once or twice a day and shutting up with heat and moisture may be resorted to.

In the Orchid collection many attractive kinds are in flower. *Stenorrhynchus speciosus* has a spike of scarlet flowers and bracts proceeding from a tuft of plain green or sometimes spotted leaves. It is a terrestrial species, and should be better known than is the case, being very showy and useful at this season. *Ada aurantiaca* strikes the attention from the bright orange colour of its flowers, a tint rare among Orchids. *Odontoglossums* are represented by several species, among others the new *O. Roezii* in light and dark varieties, and the *Lily-of-the-Valley-like O. pulchellum*. *Oncidium aureum* is a new introduction of the Messrs. Veitch. It has a bright yellow lip, and is ornamental on that account; but the sepals and petals are much reduced in size and of a pale yellowish green. *O. serratum* is remarkable from its excessively crisped segments. The flowers are large, with the petals united at their tips, of a chocolate brown colour margined with yellow. The spike is much branched and grows from 6 to 12 feet in length. *O. cheiroporum* produces a multitude of small yellow blooms, and is one of the prettiest. Quite distinct is the rose-coloured *O. oculatum*, the lip covered with purple spots, and its beauty is no less than its deviation from the usual aspect of the genus. Of *Lycaste Skinneri* several plants are in flower, one extremely dark and another very pale, the others being intermediate tints. There are also in this house *Lælia anceps* and *Cattleya Warszewiczii*, besides the very curious *Hestrepia antennifera*.

It much resembles a *Pleurothallis* in habit, but the flowers are very different. The dorsal sepal is very long and has a thickened point; in colour it is yellowish white streaked with purple. The lateral sepals are connate below with a broad blade $1\frac{1}{2}$ inch long, brownish red and thickly dotted with darker colour; easily mistaken for the lip under which it is placed. To this with the petals, which resemble the antennae of an insect, is due the singular character of the flower. These are very long and coloured like the dorsal sepal. The lip is small and inconspicuous.

In the next house is a fine plant of *Vanda suavis* with three large spikes, and a fourth in view. *Goodyera discolor* is not unlovely with its white flowers in contrast to the dark foliage. Several plants of *Phalænopsis amabilis* and *grandiflora* are coming into flower. Of *Dendrobium nobile* there are five varieties. *D. heterocarpum* is just opening. *Angraecum eburneum virens* is very useful and free-blooming, though less magnificent than *A. sesquipedale*.

APPLE TREES CANKERING—THE HAWTHORNDEN.

OUR Hawthornden Apple trees are in a similar dilemma with those of "C. R." and "AN OLD GARDENER." They are on the Doucin stock, and though the trees bear freely the fruit is very much pitted and cracked, and the branches are very much cankered, dying-off annually until the trees have a wretched appearance. The soil is a light sandy loam naturally, but has been well manured and fresh soil added, and is well drained. I have trees of this kind as standards on Crab stocks, and these are, if anything, worse in point of canker than those on the Doucin or Paradise stock—the standards are in a turfed orchard, in the reverse of an over-stimulated state from richness of soil, whilst the pyramids are not pinched for manure. Thus I have trees in rich and poor soil. Poverty of soil or its opposite extreme are not the best means of avoiding canker, yet no tree that I have seen of this valuable Apple planted within the last thirty years has done other than grow vigorously for a few years, eventually succumbing to canker, the disease spreading at a rate proportionate to the previous free growth of the trees.

In the vale of York I have seen from standard trees very heavy crops of fine unpitted fruit produced by trees anything rather than large and vigorous, they, in fact, being seldom more than half the size of other kinds of the same age. In Vale Royal I have noticed the same result—viz, moderate-sized, and I should say old trees, very free-bearing, producing abundant crops of fine fruit. All the trees I have seen uncankered and producing unpitted and uncracked fruit were certainly not planted within the last twenty years, not one that I have seen in that time doing other than fail.

Seeing that it was utterly futile to continue planting this Apple I have reserved but two trees, and upon those I intend to experiment to the last. They are, or rather were, pyramids, for one is eaten by canker almost to the stump, and is as ugly as a tree well can be. They are on the Paradise stock, and are about thirteen years from the graft. One tree I have cured of canker already in so far as respects the wood, but the fruit is still spotted and cracked. This tree is certainly not half the size of other kinds planted at the same time, but the other woe-begone subject is little beyond a bare stem, gnarled to the wood by canker, its fruit being scabbed and cracked to the core. The roots are healthy, and throw up shoots from the stock freely—proof positive that the channels of the scion are almost closed to the upward passage of the sap: hence new parts are put forth for its appropriation. There is certainly small hope of a tree such as this being restored to health and fruit-bearing, but there is a prospect of the scion originating new parts proof against canker, from not being in a diseased state, showing "a deficiency of vital energy, and consequent inability to imbibe and elaborate the nourishment necessary to sustain its frame in vigour, and much less to supply the healthful development of new parts."—(*Science and Practice of Gardening*, page 353, in which from pages 347 to 356 inclusive is admirably stated the causes of canker.)

The case is clearly one of debility. It may have arisen from over-excitement, from the use of unripened scions, and by the employment of scions taken from trees in an advanced state of decay from canker or old age; but I do not desire to enter at present upon the cause of this disastrous malady; only, as I have stated that I have not seen a healthy tree of Hawthornden planted within the last twenty years survive a bearing

state without exhibiting signs of enfeeblement and of canker, it is incumbent on me to offer such suggestions as appear warranted by experience for the prevention of its recurrence.

First, the stocks are grown in deeply trenched and highly manured soil; they are strong when headed for grafting, the scions are thus literally gorged with sap, and on them is expended the full power of the roots, and a very vigorous growth of scion ensues. Now I want it to be understood that the growth is so soft from the imperfect elaboration of the sap, and the greater part of it is unripe, if indeed the ripe part be not confined to the scion as inserted. The tree is a maiden; and if it is planted out it may be cut down to induce side shoots. In two or three years it is a bearing tree (I am alluding to pyramids), and it is sent out, planted in rich soil, and comes early into bearing. It has been over-excited and then starved into bearing, again forced into growth from a rich soil or high feeding, and nature rebels. Its conduits are closed or partially, the large channels not having in the second or third year so much nutriment passing through them as in the first, from the loss of roots consequent upon removal. Such irrational treatment results in early maturity, oftener a consequence of debility than of health, and causing enfeebled progeny and early decay.

Second, scions taken from trees in a bearing state and inserted in very vigorous out-down stocks, will have a supply of sap ill proportioned to their means of conveyance, and from weakness will of necessity be driven to the extreme of grossness. The foundation is thus laid of the future tree receiving ill supplies of sap, and becomes yearly less vigorous and more unhealthful, and succumbs slowly but surely to disease.

Third, employing soft unripe scions, which becoming dried by severance from the parent must have the vascular system contracted and disorganised; and though the supply of sap may pass this disorganised tissue in sufficient quantity to meet the requirements of the tree in a young state, it does not follow that it can transmit nutriment equal to the requirements of an extended fruitful tree.

What hope is there of a tree in the pitiful state of the Hawthornden? One only, and it is that it may, instead of giving strong shoots from the stock, put out one from the original scion, of which it shows no evidence at present; but the shoots on the stock are put out very near the junction, and I am sanguine enough to trust that the scion will eventually emanate a shoot imbued with health and vigour. I am prompted to this conclusion from having a very badly cankered *Mère de Menage*, cut off by canker to within a few inches of the junction, from which part issued a vigorous shoot, and this shoot is now a fine healthy pyramid in a bearing state, the fruit being finer than its neighbour which has had no canker but has grown vigorously and profitably from the first. Analogy further gives hope, for in cutting and pruning we originate new parts of vigorous growth; and when we have its accompaniment, ample foliage, we place far behind that debility which induces to canker, and attain to that amplitude of foliage and fertility ever presented by—**YORKSHIRE GREENING.**

STRATIFIED ROCKWORK.

As a writer in the Journal has questioned the propriety of artificial rock being made to look like natural stratification, I beg to state that where rocks are thus formed it is because it is in localities where the nearest real rock is stratified, therefore most consistent with Nature, which should be our guide, so as to avoid what is so often termed rockerywork and cockneyfied, which many gentlemen of taste have a horror of. It is the close imitation of the strata, varied in thickness and tone of colour, which is one of the charms of a rockery.

In forming rocks on this principle it is easy and usual to provide such an abundance of soil and root room with drainage that the plants thrive so well, as in a few years the rocks are not only well clothed, but often smothered up with foliage if it be not out now and then. This may be seen at many places, Battersea Park for one.

If, as "C. C. P." says, it is a mistake to try and imitate cliffs and stratification, then all our leading landscapists are wrong, as Mr. Broderick Thomas, Mr. E. Milner, Mr. Marnock, Mr. Kemp, and Mr. Gibson. They have all had it done, and none of them had it done for the exclusive purpose of growing Ferns and Alpines, but to combine, with the foliage and the rocks, a bold picturesque effect, at the same time so natural as to surprise most people when told it is artificially formed. If each stone forming the cliff or waterfall was not put

on its natural bed it would, of course, be unnatural and ridiculous.

I could name many places where the cliffs do abound—on their ledges, in the clefts and crannies—with plants so much in many places that the rock is completely hidden. This is especially so in the sandstone rock, though in most places wherever a choice plant is within reach it is carried off and the cliff made more bare. I grant that the plants thrive well among the fallen rocks and *débris*; this may be done artificially, of course, and the stones may then be placed all manner of ways.

As to Mr. Ingram, or anyone else, maintaining that all stones should be on their bed, and such having but one idea in consequence, I maintain this one idea to be imperative in imitating natural rocky cliffs. Allison, in his "Beauties of the Natural World," says "the form of rock is most sublime." Sir Walter Scott and Wordsworth were delighted among the rocks, and why? because of the grand effects; and though our imitations are comparatively puny, yet, so far as they go, will, as Sir W. Scott says, "charm our fancies' wakening hour, and deem-ing such nooks the sweetest shade the sun in all his round surveyed."

No such effects can be produced by simply scattering stones and *débris* in the way "C. C. P." desires. There must be the origin apparent, cliff or mother rock; for if, as Allison says, "rock is sublime," what shall be said of a rocky waterfall, a dropping well, a meandering stream, a noble cave, all clothed with fine verdure?

It is all very well, pleasing and interesting, to grow the pretty little Alpines or Ferns, and it is in the screens or *débris* at the base of the cliff they will do well and will be seen best; but for the rugged and bold picturesque effect or grandeur we must have the noble cliff, if only as high as our heads, so as to have the beauty of the numerous plants, great and small, that are available for growing on or about the rock so well in view, as each plant can have in well-arranged rock places suitable for every size, from the characteristic Yew or Holly down to the smallest Alpine.—**JAMES PULHAM.**

NOTES ON VILLA AND SUBURBAN GARDENING.

PLANTING FRUIT TREES.—Although the season is advancing, it is not yet too late for planting the different kinds of hardy fruit trees. I do not think many would advocate spring in preference to autumn planting, but there are no doubt numerous places where spring planting is unavoidable. At whatever time the work is done, the operation requires the greatest care.

Spring planting, and the subsequent treatment of the trees, involves more trouble and anxiety than autumn planting, because the trees have not the same time to make roots to support the growth of the following season, and consequently a little more coaxing in the way of watering and mulching will be needed. But however necessary spring planting may be, I always think it favours late growths, and then if the autumn is unfavourable imperfectly matured buds and unripened wood is the result; nevertheless there is much late planting done with good success.

The trees selected should, if possible, be those that have been previously prepared, more especially if they are large. The roots are then in a closer compass, and consist largely of fibres or feeding roots. There is less difficulty in removal, and less liability to injure the roots in removing the soil from such trees than in the case of others which have had no preparation. As the work goes on let every root cut through be turned-up and fastened to the ball of earth by a peg. This will keep them clear from the spade. Take care that none of the trees are planted too deeply, and that the stations for each are wide enough for the full spreading-out of the roots. Prepare the roots by pruning all those that may be bruised or broken. Next proceed to thin some of them out if very thick, but leave all the smaller roots, as these are the mainstay of the tree in its new home. Lay out the roots carefully and regularly, and then bed them in a little good soil prepared for them. I ought to say that the bottom of the hole should be broken up, and, if needful, have a little better soil added as an encouragement to the new roots. Work the soil between the roots with the hand, and take care that they all lie firm upon the soil. When this is done the remainder may be put-in with the spade, and in treading it down there is no danger of the roots being torn from the tree or broken.

The trees must be secured against wind by staking them. This must be done in a neat manner, taking care to place a pad of hay, or straw, or matting between the stake and the tree to prevent the bark being rubbed off. After this a watering will do good if the state of the soil in which they have been planted is well drained. The soil should be rather wet than otherwise. After this cover the surface with rough manure or

anything to act as a mulching as far as the roots extend. This may remain till it is decayed, and then it may be lightly pointed into the soil, but not so deep as to injure the roots. This covering is not intended to enrich the soil, but to act against the drought affecting the roots.

Pruning must not be done till after the trees have been planted some time, and when they have partly recovered the check caused by removal. One check at a time is sufficient, and a rest is needed by the tree before any serious pruning is given to the branches.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

INSTRUCTIONS were given last year as to the planting of fruit trees. Those who were unable to do this work at the proper time and still have trees to plant, should lose no time in having the work completed, for if it is longer delayed the young rootlets are not formed before the buds are in motion, and the growth for the ensuing season will be unsatisfactory. We always advise careful planting. All broken or bruised roots should be removed. A hole should be made large enough to allow all the roots to be spread out to their fullest extent. No better material can be obtained in which to plant the trees than decayed turfy loam. A few inches of this should be placed in the hole first, then the roots of the tree, not deeper than they were previously. Some loam should then be worked in amongst the roots with the hand, taking care to fill up all interstices. Fill the hole nearly full with the same material, and tread it down firmly with the feet. When the ground is levelled some manure should be placed on the surface to the fullest extent of the roots. This is not so much to afford a stimulant, but to retain the moisture in the soil about the roots.

We have a few Strawberry plants to put out yet. They were received in the winter, and, being a variety of which a good stock is required this season, the plants were potted singly in small pots and kept in a cold frame. When the weather is favourable they will be planted in well-prepared soil. We have seen plants sent home in the winter and laid in in the open ground, when half of them would be dead and the remainder much injured if severe frost set in before the weather became favourable enough to plant them out in the spring. A season would also be lost before a sufficient number of strong runners could be obtained. If the plants are turned out of the pots into good soil about the middle of March they will grow on at once and produce strong runners by the usual time for layering.

If the permanent fruit trees were infested with the larva of the lackey moth last season they should be looked over now, if it has not been already done, to destroy the eggs which will be found glued in rings to the smaller branches of the trees. In previous seasons we had much trouble with the Apple maggot. The garden contained a large number of old cankered trees which were annually much infested by this pest, and when these were removed the young Apple trees which were just coming into bearing sustained the attack of the enemy. One season there was a good crop of fruit, but nearly the whole of it was destroyed by the maggot. We tried dusting the trees with quicklime when the buds had started in the spring, but this made but little difference. The best and perhaps the only certain way to destroy the maggot is to pick and gather up all the fruit that has been attacked and have it destroyed. By following this plan year after year the Apples are now almost free from the maggot.

The larva of the goat moth bores into the old wood. This was also troublesome for a few seasons. It was very difficult to master it on the old and gnarled trees; indeed some of them were killed outright by it. The grubs had tunnelled the bole of large trees from the inner bark to the centre, but the young trees were watched and the maggot was destroyed before it had time to burrow deeper than the bark.

VINEYARDS.

The growths in early houses are now pushing vigorously, and much time is taken up in tying them down carefully to the wires. Most of the growths are stopped two leaves beyond the bunch. Those who have not had much experience in training the young growths will be apt to tie them down too much, which will result in some of the strongest growths snapping at night. It is very annoying to see the leaves begin to flag when the sun acts upon the glass in the morning. All the laterals should be trained in one direction, and to do this easily a strip of matting should be attached to the spurs and fastened tightly at the proper angle to the wires; to this strip the laterals are carefully tied as they increase in growth. The lateral growths will also require to be thinned-out. They ought to be opposite each other, at least as nearly as possible, and from 15 to 18 inches apart; indeed we have had the spurs 2 feet apart, and when the leaves were fully developed the distance did not seem too much.

The night temperature is now 65° both in the Muscat and

Hamburg houses. The bright sunshine the last few days has run the temperature up in the daytime to 80° and 85°. It has been necessary to admit air cautiously, as the winds have been very keen. The fruit sets very freely in such weather, but it is best to aid it a little by shaking the bunches gently once or twice a-day. There is nothing required now in the late houses. The border was not sufficiently moist in the late Muscat house, and it had some water applied to it. It is a mistake to allow the inside borders to become too dry, and we would water them at midwinter rather than it should be so.

PEACH HOUSE.

We do not mind driving the Vines a little when they begin to grow freely. With plenty of root-action and the borders well supplied with moisture they like plenty of heat, but the Peach trees will not stand it, at any rate not so early in the season. Attend to disbudding and thinning-out the fruit. If the weather should be dull and cold it is best to syringe the trees in the morning only, damping the paths, borders, and walls of the house at closing time. In bright weather, and if the house is closed between 2 and 3 p.m., the trees may be syringed at that time. The weather we have experienced lately has been very suitable to trees in blossom. The atmosphere of the house must be kept moderately dry, and air should be admitted night and day; a very narrow chink left on at the back or top sashes at night will be sufficient. The trees must be shaken every forenoon to distribute the pollen. If there were any brown scale on the trees these would be washed-off before the house was started; at the same time it is quite as well to watch for its appearance and have it destroyed by careful handwashing. No amount of syringing will either destroy this pest or the aphid that infests Peach trees.

MELON HOUSES.

Our plan in previous years was to sow Melons about the first week in January. If we had done so this year the plants would have been ready to plant out now. Last season we were not very successful with them, owing to the nature of the soil used; it was too light for Melons. To grow this fruit successfully the soil ought to be of a clayey nature, and not too rich. There are some who still prefer to train the plants over the surface of the ground, but the best way, by far, is to train the leader up to a trellis fixed near the glass. When the leading growth has reached within 18 inches of the top of the trellis it ought to be stopped. Plenty of fruit will show on the lateral growths. If the varieties are shy bearers the fruit may not show at first, but if the laterals are stopped it will show on the next growth. The Cucumbers have been planted-out. They are grown the same as Melons, except that the soil used to grow the plants in is much richer.

Figs in pots have just been placed in a house where the heat is about 60° at night. They will start strongly if carefully attended as to watering at the roots and being gently syringed overhead in fine days. Those who are fond of Figs would do well to have a house especially devoted to their culture. There is no fruit easier to cultivate in pots than the Fig, and none do better under this system of culture. The plants also do best if the pots can be plunged to three parts of their depth in a bed of leaves or tan. The heat of the bed at the bottom of the pots ought not to exceed 65°. The Fig is also different from most other fruits in this respect—if potting has been neglected it will do no harm to the trees to repot immediately before starting them, or even after the buds have started. The fruit that we usually depend upon is that formed on the young wood as soon as the growth is made. Rich soil ought to be used for potting, and a still richer material for surfacing the pots when the young growths have made some progress. At that time the roots are very active.

GREENHOUSE AND CONSERVATORY.

These structures are kept gay at this season with forced shrubs and flowers, and it is a matter of some importance not only to know how to force them but also the best way to keep them in good condition after they are forced. Flowers last long in beauty at this season if they are well managed. The forcing house ought not to have a higher night temperature than 55°; and if the plants can be removed out of this house into one with a temperature of 45° to 50° at night just before the first flowers open, and when these are fully expanded the plants removed to the show house, the later flowers will open here, and they will experience no check. The culture of the plants or shrubs the previous season is also of considerable importance. No amount of careful after-management will make up for neglect in this particular.

The most lovely of all hardy shrubs used for forcing purposes is the *Deutzia gracilis*. We grow a number of large plants. Some of them have been forced every season for the last ten years. The largest are in 11-inch pots. The plants are taken care of after the flowering period is over. They are kept under glass until the young growths are completed, and when the weather is favourable a sheltered position out of doors is found for them.

Prunus sinensis flore-pleno is also worthy of culture for its

pure white flowers. Rhododendrons of sorts are also invaluable for forcing. The plants may be lifted from the open ground, potted and placed in heat. Only plants that are well furnished with flower buds should be used for potting. They will endure a good deal of water at the roots, and to be freely syringed overhead twice a-day.

Roses are very easily forced, but they also must be well established the previous season. The plants should be freely syringed to keep off red spider. The bud worm has always been troublesome to us; but like the maggot on the Apple, it is best to destroy it by hand-picking. A pin or needle is used to pick the worms out from the centre of the young growths, where they are invariably found. The most effectual way to destroy green fly is by fumigation, repeated on successive nights until the pest is vanquished.—J. DOUGLAS.

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

LIVERPOOL (Spring Show). March 5th. Mr. R. Wilson Ker, 6, Bassett Street, Church Street, Hon. Sec.

LONDON (Spring Show). March 15th and 16th. Mr. G. Forbes, 106, Hyde Park Road, Sec.

BRISTOL (Spring Show). March 22nd and 23rd. Mr. G. Webley, Holm Wood, Westbury-upon-Trym, Hon. Sec.

TO CORRESPONDENTS.

RATING NURSERYMEN'S GREENHOUSES (A. F. G.).—We believe that they are not rateable. You will find all we have to say on the subject in our No. 639, page 188.

BONES FOR MANURE (T. W.).—The fresher they are used the better. Burnt bones are not so fertilizing, they then are merely phosphate and carbonate of lime. Rabbit's dung is a powerful manure.

GRAPE GROWING (C. de H.).—We cannot inform you whether a drawing can be had, but we shall publish further particulars.

CUCUMBER HOUSE (J. B.).—We do not know a book devoted to the subject. Keane's "Indoor Gardening," which you can have post free for twenty postage stamps, gives directions for the house management weekly.

EUCALYPTUS GLOBOSUS (W. G. M.).—We never heard of this, it is probably a mistake for *E. globulus*. We have no corrections to offer on the planting of your bed.

LIST OF COOKING APPLES (A. B. G.).—We think we did not recommend those you name. The following are excellent, and are named in the order in which they are ready for use:—Kewwick Codlin, Bedfordshire Foundling, Aldiston, and Damsel's Seedling.

FIGS FOR STANDARDS (Lady C.).—The hardiest variety is the Brown Turkey, but as your garden is favourably situated in Sussex you may also plant Brown Ischia.

SOIL FOR RHODODENDRONS (J. W.).—See notes in to-day's Journal.

PLANT COLLECTOR (W. H.).—When you have acquired a knowledge of botany, and a knowledge of all the plants at present introduced, you could apply to Messrs. Vetch & Sons and others who occasionally employ collectors. We can give you no information.

PLANTING FLOWER GARDEN (J. Gamett).—We never undertake to specify the plants for the beds, we only criticize any proposed planting. We shall be obliged by a note on ripening the Board's Deal Paper.

MAKING VINE BORDER (A. Constant Reader).—We do not advise you to mix road scrapings with your "loose, light, friable soil." If you can obtain some clayey loam to mix with it that would be of great advantage. It would be of no use to pave the border unless you concrete it at the same time; the roots would go through between the stones or whatever material was used. To every ten cartloads of your soil add one of rich decayed manure and 2 cwt. of crushed bones. Two feet 6 inches will be deep enough for the border, but you ought to have 9 inches or a foot of brickbats or some other drainage at the bottom. Barbarossa (Gros Guillaume) and Calabrian Raisin will not do for a cool house; substitute Black Prince and Buckland Sweet-water for them.

TREATMENT OF EUCALYPTUS AMAZONICA (Idem).—When your plant goes out of flower place it at the cool end of the house and keep it moderately dry until the end of April or first week in May. At that time your stove will be at least 66° at night. You should then pot the plant if it requires repotting, and water freely. A short article on the foliage plants may appear in a few weeks.

STARTING CALADAEUMS (Miss Wash).—Report them the early part of next month, using a compost of three parts turfy loam, one part leaf soil, and a half part each of old cow dung and silver sand, with good drainage, bringing them into a moist state at the roots, and gradually, as they advance in growth, sprinkling overhead frequently, and shifting into larger pots as required. When in free growth they require abundant supplies of water, and liquid manure twice a week. They succeed admirably in a stove.

SHOWING PRIMULAS, CYNORHIZAS, AND CALCEOLARIAS (Idem).—For autumn and winter forcing, Primulas and Cynorhizas may be sown in a gentle heat from the middle of March to the beginning of April, the seedlings being potted-off singly in 8-inch pots when they show the first rough leaf, keeping them near the glass in a heated house or frame, and shaded from sun until established, and in June remove to a cold frame, in which they should be grown through the summer with plenty of air and slight shade from bright sun, removing to a greenhouse in September. They should be shifted into larger pots as required. Calceolaria seed should be sown the first fortnight of July in a pan placed in a cold place and shaded from sun, pricking-off the seedlings in pans an inch apart when they are large enough to handle, and potted-off singly in 8-inch pots before they become crowded in the pans, and removing to a light airy position and cool, but safe from frost, in October, shifting into larger pots as required.

TREATMENT OF LILIES OUT OF DOORS (F. M. S.).—You may plant them

out as soon as the weather is favourable. Place some sand round the roots. It is best to leave the roots in the ground all the winter if you have a dry sub soil. Hardy perennials may be divided this month and next.

REPOTTING FERNS (F. W.).—The most suitable time is during March when they commence growing.

SETTING AUCUBA FLOWERS (S. M. W.).—Take a male plant and place it near the female; but if the plants are not in pots, or even if they are, collect the pollen of the male plants, and only when dry, and apply to the female flowers with a camel's-hair brush; but if not in flower at the same time—the male usually flowering earliest—collect the pollen on sheets of clean white paper and keep in a dry cool place until the female plants have the flowers fully open, and apply the pollen, which will adhere to the camel's-hair pencil, drawing the brush across the flowers.

EROTICUS BOYS (W. R.).—Get a summons for some of them to appear before a magistrate.

TRANSPLANTING A LARGE HOLLY (F. Y. Dutton).—Provided there is no obstacle to lifting with a good root and a good ball, as there may be from looseness of soil and proximity to large trees, we see no objection to its lifting safely, being careful to preserve all the roots possible; to water carefully, not solidening the soil, but keeping moist, and securing against winds, cutting-in the head considerably at planting, which will afford opportunity of bringing the head into good shape. If not cut it is likely the tree will have many of the branches die back, or from poor growth have a miserable appearance for a number of years, even if it recovers from the removal. Select for the operation moist weather during the early part of April, just when commencing growth.

CAMELLIAS FOR BACK WALL OF VINERY (W. A. R.).—Camellias planted in a vinery started the first fortnight of February would succeed, but they would flower in early autumn. Unless the plants are a good size to commence it would be a considerable time before they would have grown to make "a show" of much consequence. They would not be effective for half a dozen years. A few good kinds are—Bononiensis, Countess of Derby, Conspecta, Mathotiana, Mathotiana alba, Redoulata rose-pleno, Monarch, Valdivaredo, and Mrs. Cope.

PLANTING RHODODENDRONS (Idem).—From now up to and including April is a good time to plant these, but the earlier it is done the better, mild weather being chosen.

CULTURE OF DEUTZIA GRACILIS AND SPIREIA JAPONICA (E. L. L.).—Both ought to be potted and introduced to the greenhouse in January, affording them a light airy position. They should be watered moderately until in free growth, and then copiously, the Spiraeas requiring a very abundant supply after the spikes rise, and they are aided by weak liquid manure at that time. After flowering the Deutzias should be placed outdoors in an open situation, and be well supplied with water during summer, the pots being plunged in ashes. When the leaves fall repot the plants, removing a great part of the old soil, and repot in the same or a slightly increased size of pot, and plunge in ashes over the rim of the pot, introducing a part of the plants to the greenhouse in January, and another batch a month later. The Spiraeas after flowering to be planted outdoors in good rich soil, and well watered during dry weather. After they die down in autumn take them up and pot, plunging over the rim of the pots in ashes, and introducing to the greenhouse in January and February. Turfy loam, with a fourth of leaf soil and well-decayed manure, will grow them well.

GERANIUM LEAVES SPOTTED (G. H.).—The leaves are spotted, but not badly. It arises from too close, cold, and damp an atmosphere. Keep drier and warmer, admitting air freely, and with brighter and warmer weather the plants will come all right.

CYNORHIZAS (John Lowley).—The Cynorhiza flower buds you sent us are not as you apprehend, "blind," but will in due course flower, they being much too backward to do so for a month or six weeks. Assign them a light and airy position in a greenhouse, they appearing to be drawn and weak.

SMOKEY-DISTRICT FLOWER BORDER (W. J. Taylor).—The arrangement is good, and the plants will answer tolerably well. Had we to contend with your murky atmosphere we should rather depend upon foliage than blossom, planting in a very open gritty soil to afford a free passage for superfluous water in order that no harm should arise from the frequent syringing which is really requisite to keep the foliage healthy and clear, and the colours bright. If this is done regularly say twice or thrice a week, the deposit of soot—carbon—upon the foliage is washed down to the roots, and a fount pest is thus converted into nutriment. The crimson leaved Ilex Lindleyi would answer well as a substitute for the Geranium. Antennaria tomentosa forms a neat edging of silvery grey; it is perfectly hardy, and spreads quickly. Leucophyton Brownii and Santolina incana are also choice grey-leaved plants with elegant xanthic foliage and a dense compact habit of growth. Mesembryanthemum cordifolium variegatum, a succulent with pale yellow-margined leaves and dense-spreading decumbent growth, and the two pretty little golden varieties of Arabis—A. incana variegata and A. albidula variegata, would also answer well. Both of the latter are quite hardy.

NAMES OF FRUITS (W. G.).—The Pear is Uvedale's St. Germain, and is used for stewing; 4, Rainette de Canada; 5, Claygate Pearmain; 6, Golden Noble.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE SALE SYSTEM AT EXHIBITIONS.

THIS present temporary lull of poultry and Pigeon shows, while the breeding season is going on, seems the opportunity for fanciers of every kind to give any hints to committees and managers of exhibitions that they think advisable for the better conducting of their meetings. There are many schedules of shows which need entirely remodelling, especially of agricultural exhibitions, for there the officers are often cattle people, who do not know whether it is the most advisable to give a class for Brahmas or Polish. Now, the fanciers and amateurs of the districts of their own meetings generally know the strong points of their county, and they should try to get their old-fashioned schedules, which are behind the time, remodelled and made to suit more the existing wants of the times. They can do this much better among themselves than by having recourse to the

papers on poultry; for even could the various organs give space for such correspondence, which if at all taken up in the way it should be would be immense, the local committees of agricultural shows, which are after all the greatest delinquents in being behind the times, would many of them not see such hints, and if they did be probably unwilling to act by them.

Not only in the matter of classification should the fanciers of the district where the various shows are held work for this cause, but to obtain the latest and best new rules and regulations. Some societies put out their old rules year after year, and wonder why their entries dwindle, and that "there ain't so many cocks and hens as last time;" utterly ignorant that now fanciers want double baskets, lower entry fees, the names of the judges, early despatch of catalogues, &c. These matters, then, we leave more to the various agricultural meetings' poultry friends; but there is a point which requires a more general reform, for more than half the existing shows fall in this respect, and so we venture ourselves to call the notice of managers of exhibitions to it. We allude to the present sale system of birds at the catalogue prices.

We should think almost the youngest fancier must have experienced some trouble in this line. We know we have ourselves over and over again, and so have dozens of our friends. Those shows which have auctions we say nothing of; theirs is as satisfactory an arrangement as can be made, and we only *en passant* recommend some of them for their fund's sake to put up as well all the highly commended pens which are not entered above £2 or £3. If once they have the expense of an auction they may as well do this, and it would not take much more time and might bring in more grist to the mill. Few exhibitions, however, are large enough to afford or make it worth their while to sell, or rather put up their birds to auction, and it is of them we write.

There are two or three plans at present in practice—namely, for the first comer at the appointed time of sales to have the pen he wants; or by tender; or again, by the highest bid made at one and the same time having the birds. Against the first system we cannot say too much. We have seen a dozen people all clamouring for a bird, and all declaring they were the first-comers; or we have seen people stand for hours at the door, and then be told, after all the waiting, that the bird is sold. Who the purchaser is, history telleth not; but those naughty little birds will whisper, "Committeemen." The second plan, that of tender, is in many ways satisfactory and good. They tried it at Oxford last season, as have other shows, and we hear they found it to work successfully and satisfactorily; but it has one great drawback—namely, the office has to be open three or four hours to receive the tenders; and by the time the highest are declared many of the exhibitors from a distance have had to leave, and do so ignorant as to whether they have secured the bird or birds; and very possibly, had they known one way or the other before leaving, they would have bought other specimens in the event of not having obtained what they wanted by their tender. Over and over again it happens that there are some two or three pens in a show at a ridiculously low price. Everyone wants them, and a rush is made for the bargains; and it is very tiresome and awkward for the committee, where this old system of first-comers being first served, to know who is really entitled to the pen. We shall never forget the excitement and eagerness of a dozen exhibitors to get some Spanish at Oxford in 1874; and whether the first-comer had the pen or not we do not know, but all we do know is that every Spanish breeder for the rest of the day declared that they ought to have had the bargain.

Well, now, we should try and put a stop to this; and we believe, for the average run of shows, the third of the three plans we named would best answer all ends—that of letting the highest bidder have the bird. We do not mean the highest bid in the day, but the highest made at the one and the same time. Suppose, for instance, a pen was in at 50s., and A, B, C, and D wanted it. If, when the office opened at the appointed hour, the highest bidder of A, B, C, or D, had the pen no one could grumble. This must, however, be stated as to take place in the printed rules, or the results would be worse than ever. We believe this plan would find favour with most people, and it would at any rate prevent the needless waste of two or three hours at the secretary's door for the office to open, as so often takes place, and sometimes too without any good. It would also lessen the troubles of the secretary; and above all, everyone would surely feel satisfied when they knew that at least the highest sum obtained the bargain. We venture to suggest this to committees as a new rule to those who are in want of some such one, and who are now framing their schedules anew, believing that while exhibitors and fanciers will welcome it, managers will find that by it much annoyance and trouble is taken off their shoulders.—W.

THE JACOBIN.

It had not been my intention to write another word on this subject. The vast majority of fanciers are agreed in accepting

Mr. Fulton's description of the bird in his new work, and Mr. Ludlow's admirable portraits in the same work, as their standards; the minority have used their proper privilege of stating their views: here matters naturally end. A minority has in England on all subjects a certain degree of influence, but no power unless they are able in time to become the majority.

But as Mr. Harrison Weir has challenged my statement in regard to another bird—the Turbit, I feel I must "bring him to book." All the works on fancier Pigeons are before me as I write. Moore, A.D. 1735, states that the Turbit "has a round button head," but no word about a crest shell or pointed. The "Treatise," A.D. 1765, states the Turbit "should have a round button head;" and in the portrait of that Pigeon, the first ever known to have been made, shows the bird with round head indeed, but not an atom of crest. The work by Girtton A.D. (according to the British Museum authorities) 1800, gives the same account and a picture equally minus a crest. Eaton's work, A.D. 1858, with notes by Brent, states "They are usually smooth-crowned, though some are point-headed, and others have tolerable hoods." That the first was the rule is shown by the portrait in the same work by Mr. Wolstenholme, who certainly knew the Pigeon of his day better than any man, which is without any crest whatever. Then comes Mr. Brent's own work, published in 1880 I think, with second and third editions reaching to this time, and the portrait in this book also is minus any crest. In the letterpress Mr. Brent states, "Some Turbits are point-headed, others are turned-crowned, but one is considered as good as the other, though I regard the smooth head as the original." Next we come to Mr. Tegetmeier's "Pigeons," published in 1868, where for the first time the Turbit is pictured with a point head, and a great improvement I think it is. Then follows the Birmingham Columbarian portrait in this Journal of April 6th, 1871, with point crest, and then Mr. Fulton's with same and shell.

I distinctly remember in about 1840 seeing Turbits plain-headed, then afterwards shell, then point. Thus improvements were progressive in this bird as in the Jacobin, in which, thanks greatly to Mr. Esquillant, the rose and mane have become established, other fanciers assisting. Progressive, gradual, well-considered improvements there should be.

I am very sorry that Mr. Weir should have thought any word of mine uncourteous, and certainly any reference to old men could not apply to him. There are writers whom I should never think of answering, but Mr. Weir is one of a different stamp, and deserves what I am happy to give in his case—a reply. I have just been looking at Mr. Weir's beautiful "head of Jacobins," the uncoloured one in "Pigeons," and admire it much, and he gives almost as good a mane as could be desired.—WILTSHER RECTOR.

PULLET EGG-BOUND—SPANISH COCK'S FACE SPOTTED—POULTRY DIET.

I HAVE a fine Buff Coochin pullet that tumbles about in a remarkable manner which I took to be leg-weakness, but in the Journal of the 27th I found an answer which just suited my case. I immediately inserted a feather dipped in castor oil, also gave the pullet a good dose, but with no good result. Next day I drenched her with oil in the egg-passage, besides giving her a large tablespoonful to drink. I inserted my finger, and certainly felt the egg apparently covered with a sort of envelope. I can also feel it outside. I feed her on bread and milk. She is in perfect health, eats, drinks, and looks well. I should like to save her, what must I now do? She has been a fortnight in the state described.

What is the cure for canker? I have a Spanish cock having a rusty spot eating its way into the white earlobe.

Will you also give me your opinion on this? I have Cochins, Dorkings, and other fowls in enclosed good runs, well housed at night, fed each morning with hot food consisting of refuse from a gentleman's kitchen boiled up and thickened with bran; in the afternoon with the best oats whole; on each occasion as much as the fowls can eat. They are from eight months to three years old, and in number about thirty, but produce no eggs.—W. BLACKSTOCK.

[You must continue the application of the oiled feather. It must succeed; we have never known it fail. We do not advise you to touch the egg. The shell before it is laid and comes in contact with the atmosphere is very delicate, and if broken in the passage generally makes a fatal case. It is then rarely laid; and if it is, the broken shell lacerates the delicate membrane through which it passes. You need give no oil internally.]

If the Spanish cock is with hens remove him till the spots have disappeared, or the hens will eat his face. Wipe the spots very dry and then dust them with powdered alum. If the face bleeds you must treat it with citrine ointment.

We do not like your dietary. Feed in the morning on slaked barley meal or ground oats. At midday give the household scraps; if they run short, eke out with barley or maize. No oats whole; fowls do not like them, and bran is the worst food

you can give. Give an evening meal same as morning. You will then have eggs.—Eds.]

KENDAL AND NORTH-WESTERN COUNTIES SHOW OF POULTRY, &c.

This was held on the 10th, 11th, and 12th inst., when the following awards were made by the Judges:—

DORKINGS. Coloured.—Cup and 8, J. Walker. 2, Mrs. T. W. L. Hind. 3, L. Pilkington. Silver-Gray.—1, Hon. Mrs. Howard. 2, G. Maples. 3, M. Raines. Coloured.—1, J. Walker. 2, Mrs. T. W. L. Hind. 3, L. Pilkington. Silver-Gray.—1, J. Walker. 2, W. W. Rutledge. 3, Hon. Mrs. Howard. **BRAMA** **POULTRY.** Cock.—Cup, T. F. Ansell. 2, J. F. Smith. 3 and 4, M. Raines. 4, F. E. Gibson. **Hen.**—1, Newham & Mandy. 2, J. F. Smith. 3, R. Rayner. 4, J. Parry. 5, Mrs. Holchkin. **COCHINS.** Buff.—Cock.—Cup and 2, J. Walker. 3, G. H. Proctor. **Hen.**—1, J. Walker. 2, H. Tomlinson. 3, J. O. Rigg. **Chick.** 1, Hine. G. H. Proctor. J. Cattall. **Any other variety.**—Cock.—1, H. Lacy. 2, H. Tomlinson. 3, J. Both. **Hen.**—1, J. Walker. 2, G. Bloodworth. 3, J. F. Clarkson. **Chick.** 1, J. Wood. **GAME.** Black-breasted or other Red.—Cock.—1 and 2, J. R. Fletcher. 3, W. & R. Adams. **Cockerel.**—Cup, S. Matthews. 2, T. Burgess. 3, J. Pennington. 4, R. B. Hudson. **Any variety.**—Cock.—1, R. Hawkins. 2, J. R. Fletcher. 3, D. Harley. 4, J. Nelson. **Hen.**—1, H. A. Clark. 2, H. A. C. W. Brierley. 3, J. Cook. 4, E. Windwood. 5, J. R. Fletcher. **Black-breasted or other Red.**—Cup, S. Matthews. 2, W. Higgins. 3, E. Aykroyd. 4, W. Chambers. **SPANISH.** Black.—1, H. Beldon. 2, J. Loening. 3, C. R. Kay. **HAMBOURG.** Golden-spangled.—Cup and 2, G. G. Cartmel. 3, C. R. Kay. **Chick.** 1, T. Desh. **SILVER-SPLASHED.**—1, A. Stirling. 2 and 3, J. Fielding. **Golden-pencilled.**—1, H. Beldon. 2, G. & J. Duckworth. 3, J. Gilmour. **Silver-pencilled.**—1, R. W. Bracewell. 2, H. Beldon. 3, J. Ashworth. **Black.**—1, H. Beldon. 2, R. L. Garnett. 3, A. Trickett. **ANY OTHER VARIETY.**—1, A. & W. H. Sylvester (Golden Poland). 2, H. A. Clark. 3, H. Beldon. **Chick.** 1, G. Woods (Crève-Cœur). H. Robinson (Houdan). W. Jackson (Crève). **SELLING CLASSES.**—Cock or Hen or Drake and Duck.—1, G. G. Cartmel. 2, T. F. Ansell. 3, J. R. Fletcher. 4, R. Yardey. 5, Mrs. T. W. L. Hind. **Chick.** 1, W. Badger. **Cock and Hen or Drake and Duck.**—1, G. Cartmel. 2, J. D. Nicholson. 3, H. Yardey. 4 and 5, R. L. Garnett. **Chick.** 1, G. Gibson. A. Crosthwaite. H. Dean. **GAME BANTAMS.** Black-breasted and other Red.—Cock.—1, Mrs. J. Winkill. 2, J. R. Fletcher. 3, W. F. Addie. 4, R. Brownlie. **Hen.**—Cup, R. Braithwaite. 2, J. R. Fletcher. 3, H. J. Nicholson. 4, W. F. Addie. **Any other variety.**—Cock.—Cup, J. Barlow. 2, Bellingham and Gill. 3, J. G. Cartmel. 4, R. Brownlie. 5, J. Winkill. **Chick.** 1, S. G. Coulthard. 4, J. R. Fletcher. **BANTAMS, OTHER THAN GAME.** Black.—Cup, W. H. Shackleton. 2, J. Walker. 3, C. & J. Illingworth. **Any other variety.**—1, H. B. Smith. 2, H. Beldon. 3, J. Walker. **GREEN.**—1, J. Walker. 2, T. W. L. Hind. **TURKEYS.**—1, W. Wykes. 2, J. Walker. **Ducks.**—Rouen.—1 and 2, J. Walker. 3, J. Brookwell. **Aylesbury.**—Cup and 2, J. Walker. 3, W. Wallace. **Any variety.**—1 and 2, J. Walker. 3, M. Lead. **SPECIAL PRIZES FOR LOCAL EXHIBITORS.**—Mr. E. H. Wilson's Piece of Plate for the best Pen in Local Classes was awarded to T. J. Harrison. **DORKINGS.** Chickens.—Cup, Hon. Mrs. Howard. 2 and 3, Mrs. T. W. L. Hind. **BRAMA** **POULTRY.** Chickens.—1, P. Cartmel. 2, G. Cartel. 3, J. Somervell. **COCHINS.** China.—1, T. J. Harrison. 2, G. E. Cartmel. 3, R. Cornthwaite. **GAME.** Cockerel.—Cup, J. W. & T. Parker. 2, H. Leighton. 3, J. C. Parker. **Pullet.**—Cup, H. L. Hindson. 2, H. Leighton. 3, J. W. Tyson. **Foreign.**—1, G. Kirkbride. 2, J. Shaw.

BYEWAYS OF EXPERIENCE IN MANAGING BEES.

A SUGGESTED plan for securing the largest possible quantity of honey which recently appeared in the American "Bee-keeper's Magazine," recalls certain experiences of my own in past years, which in a measure support the plan and induce me to scribble off a few paragraphs on the subject.

"The plan is simply to keep a very strong stock queenless during the period of the greatest flow of honey."

Everybody knows that there is a sort of rivalry going on in every prosperous hive during the months of May, June, and July between the queen bee and the common worker bees as to which of them shall be the first to occupy any vacant cells that may happen to be in the hive. For a time—I may say at different times—during the summer, for a week or ten days together, the queen has it all her own way—that is, when there is no honey in the flowers above the daily wants of the community; then the queen bee fills every available cell with eggs, and the whole energy of the hive is devoted to rearing young bees. But no sooner is there a superabundance of honey in the fields and gardens than a change comes over the "spirit of their dream." The young, it is true, are not neglected; but every bee that can be spared for the work rushes off in frantic haste to make the most of the golden harvest which lies secreted in the million flowers around, and every cell that can be laid hold of is quickly filled with the precious nectar. It is at this time the rivalry I have alluded to takes place between the queen and her subjects. There is no doubt that the increased heat of the hive at this busy time develops and quickens the natural functions of the queen. Then it is she lays sometimes many thousand eggs in a single day, and her impulse is to find a home for every egg in a suitable cell. I have even seen her at such times, when none are to be found empty, sit disconsolate on the edge of a comb and lay her eggs at random, only to be devoured by the attendant bees.

Equally troubled in their different way at such times are the worker bees themselves. The sudden influx of honey which follows upon a favourable change of weather at the favoured moments, few and far between, which our fickle climate gives us, often finds the hive totally unprepared to garner with efficiency the precious harvest. Every cell is full of young bees, and the queen is roaming about watching her opportunity to re-occupy the cells as fast as they are untenanted by the exit of the adult young. At night time she is mistress of the situation, and makes the most of the enforced cessation from honey-gathering on the part of the workers.

It will thus be evident that, however fast the bees make fresh comb in supers or elsewhere, there are times not seldom occurring when a heavy loss in honey is sustained owing to the great fertility of the queen, which prompts her to anticipate the workers and overfill the cells with brood.

The question arises—it has often suggested itself to my own mind—Can we in any way meet this difficulty and check the proceedings of the queen, so as to give full opportunity to the bees? I believe this can be done, and there are several ways of compassing this desirable object. One way is that which I have referred to above in language quoted from an American source. My own experience as a bee-keeper leads me to believe that the removal of a queen from a vigorous hive at the commencement of good honey-gathering weather will usually be followed, if the thing be well managed, by a marked and unusual increase in the harvest of honey as compared with other hives in the same apiary not so treated, even though they may be more populous and strong.

Scarcely a year has passed in my experience which does not recall some instance in which a hive that has lost its queen (no doubt unawares to the bees, as not unfrequently happens) has been found heavier and to contain purer honey than more active and stronger hives in which the queen has been in full activity. How many are the instances, too, in which hives have been found in the late autumn to contain a large quantity of recently collected honey while absolutely tenantless; and this in many an instance doubtless owing to the same cause—the queen had died or been lost unperceived by the bees, who themselves died away almost suddenly in large numbers at the last. The removal of a queen is the difficulty. It may, however, be easily done at swarming time, by which means the swarm, returning to the hive, will generally have several days of uninterrupted honey-gathering before the development of the next queen and the issue of the swarm again. In this case, of course, plenty of room should be given in supers or elsewhere to allow the bees full opportunity for collecting and storing honey.

I should never advise any violent treatment of the hive, as by driving or fumigating with a view to secure the person of the queen; more harm than good would result from it. A queen, however, may often be seen and caught in a super with glass windows, without the bees discovering her loss for many days, in which time much honey may be collected, as also afterwards during the long period that must elapse before the development of the young queen, in the case of their subsequent discovery of their queenless state.

Another way of securing the same object is to entrap the queen in a super, which may then be placed over an adapting board on the hive with passages so narrow as to prevent the queen from descending, while the worker bees have just space enough to pass up and down. A third plan for meeting the case is to put the queen into a "queen cage," and confine her in the very heart of the hive or in a super as long as may be thought necessary. In this case she could be restored to her subjects by being set at liberty on the cessation of the honey-gathering period.—B. & W.

THE WONDERS OF A BEE HIVE.—No. 5.

In my last letter I took a hasty glance at the idleness, sufferings, and sorrows of drone bees, and their melancholy end; I now come to notice a more pleasing theme—viz., some of the habits and characteristics of working bees. There is really so much that is interesting and instructive in their history that one hardly knows how or where to begin, and it is likely that when a commencement is made a greater difficulty will be found in making a finish.

Though poets and historians of all ages have sung and written about the works and ways of bees, the subjects on which they delighted to dwell are still as fresh and novel as ever they were. The things that are seen and approachable in bee history are quite as marvellous as those that are unseen and unapproachable. Yes; notwithstanding all that has been written about bees in bygone ages, and all that may be written for ages to come, all thoughtful students of bee history during the next century will find a world of wonders and mysteries to engage their attention and excite their admiration.

What a wonderful manifestation of industry do we find in a bee hive! What architectural skill is displayed in the formation of cells and the structural arrangements of combs! Talk about a palace of marble or a city of granite, where shall we find any-

thing produced by the mind and hand of man equal to a city of wax—the habitation of a swarm of bees? What else can be compared to it for economy of space and materials, for beauty and cleanness, and for adaptation of means to an end?

It should be borne in mind that the operations of bees are accomplished in the absence of light. They need neither the light of the sun by day or of the moon by night for indoor labours. Inside a bee hive all is darkness, and yet with what unerring exactness and exquisite finish everything is done! No worker in the community needs to serve one minute of time as an apprentice, for the youngest worker is as skilful and qualified as the most aged and experienced.

What an amount of work is done by a swarm of bees! What countless offices and services which cannot be named or classified are willingly and cheerfully performed by the workers every hour! The heaviest work of the bees may be classed under three heads, viz.,—1, comb-building; 2, the rearing of brood; 3, the gathering and storing of honey; and these go on simultaneously.

In honey weather a very large swarm put into an empty hive will build and finish from 5000 to 10,000 cells a day. During the first forty-eight hours some time is lost in laying the foundations of the combs and getting some fairly begun. Afterwards comb-building goes on with great rapidity. Moreover, the bees have to create the materials (the bricks and mortar) of the combs. Wax is not gathered, it is a secretion of bees and costs them much toil and honey. What industry is manifested by our illiterate servants in ranging fields and forests for honey wherewith to find both food and "furniture" for their homes! And as soon as cells are constructed they are filled with either honey, or brood, or pollen.

Let us now think of the toil of nursing. Young bees need a great deal of food and nursing before they are ten days old. During these ten days food enough is put into their cradle cells to rear them up to full-grown adult life. Every little grub (and there are at least one thousand produced daily) requires food enough to fill its cell before it is sealed up at the end of ten days. How carefully the food is mixed and kneaded before it is given to the young! and all this is done by foster-mothers—the working bees. The maternal duties of the queens (the real mother bees) extend no further than the production and laying of eggs; and we lately have seen that in this work of production the physical powers of queens are heavily taxed. The industry of bees can never be compassed by man; his highest conceptions fall far short of the reality.

Let us now have a few words on the sagacity of bees. No bee-master need rack his ingenuity to find evidence of the sagacity of bees. It may be noticed in the shape and formation of their cells, which dip or slant downwards. Cells are made for both brood and honey, and of course answer admirably for cradles and store-room. If for breeding purposes merely, they would have been probably made quite horizontal, but if made quite horizontal they would have been more difficult to fill with honey; but the bees have wisely given them a dip, so that they are more easily filled with, and are better receptacles of, honey. If a bit of guide comb be given to bees, with the slant running upwards, they accept the comb but reverse the dip of the cells. See also the ladders used by bees to shorten their journeys indoors. If a swarm put into an empty hive do not nearly fill it, the bees let down two or three ladders or ropes of bees on which the outside workers can more readily ascend to the store-rooms.

What thoughtful care is often manifested by the bees of full hives in cold spring days and nights! At this season bees are instinctively anxious to multiply their numbers as quickly as possible, and set eggs in as many cells as they can cover. If the weather become very cold bees cluster in the doorways, and thus make excellent sandbags to preserve the heat of the hives and save the brood from being chilled. In going to and returning from the fields what ingenuity is displayed in windy weather by bees! They cannot fly against the wind. They will go round the base of a hill, even if it is a mile farther, than over it. In such weather bees seek the shelter of banks and hedges, and may be often seen flying at great speed along open ditches; and when there is no kind of protection to be found, they fly so low that it may be said of them they are kissing the surface as they fly along. The sagacity of bees is sometimes evident when there is a scarcity of flowers in their neighbourhood, or a superabundance of bees for the honey flowers. How frequently have we seen bees disappointed in going from flower to flower in search of honey. They were too late; others had secured the sweets. After trying several flowers without success, we have seen them rise like a rocket and go to another part of the field.

Instances of sagacity may be often witnessed in the preparations made for swarming—in the alterations of their programme—by resolving not to swarm owing to unfavourable symptoms after preparations have been made, also in their attempts at housebreaking and robbery. And what shall we say of bees when they find that their hives and homes are lazar houses of foul brood so unendurable that they abandon them to seek a home elsewhere, and it may be in a strange country?—A. PATTISON.

OUR LETTER BOX.

ENCLOSURE FOR FOWLS (H. C.).—A fence of strained wire netting, large-meshed, 6 feet high, will answer your purpose (if one wing be cut), and effectually confine your hens. The wings may be cut at once, and will not require to be done again till after the next moult. The feathers should be cut down to the quill, but not lower nor into it. You may choose among Spanish, Hamburgs, Houdans, and Orpingtons. For ordinary purposes, and for layers only, we prefer the two latter, and of those two the last.

DEAF EARS OF HAMBURGERS (J. D.).—However good the parents may be in white deaf ears, there will always be some chickens that are inferior, but they will be very few. They fall off in moulting time. They acquire a red tinge if they are much driven about, but we have always found that if we bred from good parents we have had good birds. Our experience of family ears is, that a little falling in that respect is often overlooked for the sake of other valuable properties, and the fact is forgotten that defects are more certainly transmitted than virtues.

VOLUNTEER SHOW.—Mr. J. Biddle informs us that his Dark Brahman pullet won the fourth prize.

BARLEY SUGAR FOR BEES (Roselle).—Barley sugar can best be given to bees by thrusting a stick at a time in among the combs at the entrance of the hive. Take care to leave the entrance unblocked by the barley sugar.

QUEEN-RAINING.—"J. O. H." In answer to a correspondent, says that full directions are in Mr. Hunter's "Manual of Bee-keeping."

REMARKS.

- 9th.—White frost; fair but very cold all day; less windy towards night; no fog here, but very thick and black in town.
10th.—White frost in morning; fine all day; slight fog between 7 and 8 P.M., but soon cleared off.
11th.—Very dense fog all day, and at times very dark, but the sun seen plainly through it, so that it was not cloud but fog that made it so dark; in London it was fearfully dark.
12th.—Rather foggy early, but a very fine bright day, though very cold.
13th.—Fog, but soon cleared off, a bright pleasant day; snow commenced a little before 7 P.M., and ceased at 9; nearly 8 inches deep fell in these two hours.
14th.—Fine morning, snow still on the ground; a very fine pleasant day, but rain in the evening.
15th.—Rain all the early part of the day; fine afternoon; but rain again in the evening.
A cold week, especially the 11th, on which day the temperature did not rise to freezing even by the sun thermometer.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 16.

PRICES of all kinds of best fruit have an upward tendency, the supply getting shorter. The market is well stocked with early-forced vegetables, the Channel Islands sending good samples of Ashleaf Kidney Potatoes.

From observations taken near London during forty-three years, the average day temperature of the week is 47.8°; and its night temperature 53.8°.

CULTURE OF CROTONS AND MARANTAS FOR EXHIBITION.

THE first-named genus of ornamental-foliaged plants is well adapted for exhibition purposes, and the species best adapted for that purpose are of very easy culture. The staple potting material is good turfy loam from an upland pasture. The turf should be cut thin and stored for about three months before using it. One-third of the compost should be turfy peat, with a little silver sand added, and I have found some broken crocks mixed with the soil to be beneficial. The Crotons require a considerable supply of water during the growing period and a highly moist atmosphere; 70° at night during the summer and autumn months is a suitable temperature. The pots must be well drained: not only is this of the first importance when the plants are repotted, but some of the fibrous peat should be shaken free from soil and carefully placed over the drainage before putting in the compost. I have seen small plants which had been potted in fine soil produce by far the largest proportion of active roots in the drainage.

Crotons are very much a prey to insect pests. The plants must be kept clean, else the beauty of the foliage is sadly marred. Mealy bug is the worst to deal with, and if this gains a footing on *C. angustifolium* the plant had better be destroyed. Some of the large-leaved species may be cleansed by careful washing by hand with soapy water. Red spider is another formidable enemy if it is not observed in time. Syringing the plants daily with clear tepid rain water will keep it in check; but if this is done carefully from the first the spider will either be destroyed, or will not increase enough to do harm. Brown scale also fastens on the stems and does mischief if it is not removed by hand-washing.

Then, as to the position in which the plants should be placed. Who has not admired the splendid specimens of *C. angustifolium* at the metropolitan exhibitions, its pendulous leaves piled one over the other, and drooping gracefully until the tips of the leaves touch the ground? while as to the colour, one may well quote the words of the poet, describing the doors of the chariot that was sent to convey home the spirits of the old Scottish Covenanters. They were—

"bright and shining,
All dazzling like gold of the seventh refining."

But to obtain the leaves of this bright golden tint the plants must be placed close to the glass, and be exposed to full bright sunshine. I will name a few only of those best adapted for exhibition. Besides *C. angustifolium* alluded to above,

C. variegatum is a very old-established species, and when well grown the glossy green ground colour of the leaves sets off to advantage the rich gold of the margins and midribs.

C. Wiemannii is of recent introduction, and has already proved to be a grand species for exhibition. The leaves

No. 778.—Vol. XXX., New Series.

retain their splendid golden colour under shade, but when the plant is exposed to the light the leaves are of the brightest gold.

C. undulatum when well grown is also a splendid species. The leaves are large, wavy, beautifully variegated in their different stages with yellow, pink, and crimson.

C. majesticum is a noble species of more recent introduction still; the leaves gracefully recurve or droop, and the whole plant is very graceful. The colour is olive green and yellow, which latter colour changes to crimson as the leaves become older.

The above selection is amply sufficient for exhibition purposes if they are shown simply as foliage plants. If a class is devoted to this genus alone, say six sorts, then others would require to be added. *C. ovalifolium*, *C. Veitchianum*, *C. Youngii*, and *C. maximum* are distinct and first-rate.

MARANTAS are also well adapted for exhibition, the foliage of some of the species is strikingly beautiful, and the plants have distinctive features of a high character. Indeed, whether for exhibition or for the decoration of the plant stove, they are indispensable.

The treatment as regards potting and watering is the same as for Crotons, except that the potting material should be mostly of turfy peat, to which a third of turfy loam may be added. The plants must not be exposed to the sun, but require the usual shade given to stove plants in general. Water abundantly when the plants are in active growth, and maintain a high moist temperature.

I will name only a few of the best sorts. At the top of the list must be placed *M. Veitchiana*. The plant when full grown is over 8 feet in height. The under surface of the leaves is purple, which shows through to the upper side, which is beautifully marked with blotches of yellow and greyish white. This is altogether a splendid-foliaged plant. *M. illustris*, *M. Lindeniana*, *M. rosea picta*, and *M. Van den Hecke* are all fine sorts.—J. DOUGLAS.

CHRYSANTHEMUMS AND THEIR CULTURE—
"EXTENUATING CIRCUMSTANCES."

No. 1.

Few, if any, plants during their season of flowering are capable of producing such a gorgeous display as do Chrysanthemums. They produce also, it must be added, not unfrequently some disappointment. Let me explain, for the matter is worthy of being alluded to for the information of employers, and as just to the employed.

I have been many years a grower of Chrysanthemums; and while I was as successful as my neighbours and was not often found fault with, still my employer seldom failed to let me know that his blooms were inferior to those he had seen at the metropolitan exhibitions of this flower. At that time I had not seen one of those exhibitions. Last autumn, however, a visit to "town" enabled me to see the plants at the Temple and also those in some of the principal nurseries.

My first visit was to the Temple, where I found a glowing display, and many ladies and gentlemen taking names

No. 1430.—Vol. LV., Old Series.

thing produced by the mind and hand of man equal to a city of wax—the habitation of a swarm of bees? What else can be compared to it for economy of space and materials, for beauty and cleanness, and for adaptation of means to an end?

It should be borne in mind that the operations of bees are accomplished in the absence of light. They need neither the light of the sun by day or of the moon by night for indoor labours. Inside a bee hive all is darkness, and yet with what unerring exactness and exquisite finish everything is done! No worker in the community needs to serve one minute of time as an apprentice, for the youngest worker is as skilful and qualified as the most aged and experienced.

What an amount of work is done by a swarm of bees! What countless offices and services which cannot be named or classified are willingly and cheerfully performed by the workers every hour! The heaviest work of the bees may be classed under three heads, viz.,—1, comb-building; 2, the rearing of brood; 3, the gathering and storing of honey; and these go on simultaneously.

In honey weather a very large swarm put into an empty hive will build and finish from 5000 to 10,000 cells a day. During the first forty-eight hours some time is lost in laying the foundations of the combs and getting some fairly begun. Afterwards comb-building goes on with great rapidity. Moreover, the bees have to create the materials (the bricks and mortar) of the combs. Wax is not gathered, it is a secretion of bees and costs them much toil and honey. What industry is manifested by our illiputian servants in ranging fields and forests for honey wherewith to find both food and "furniture" for their homes! And as soon as cells are constructed they are filled with either honey, or brood, or pollen.

Let us now think of the toil of nursing. Young bees need a great deal of food and nursing before they are ten days old. During these ten days food enough is put into their cradle cells to rear them up to full-grown adult life. Every little grub (and there are at least one thousand produced daily) requires food enough to fill its cell before it is sealed up at the end of ten days. How carefully the food is mixed and kneaded before it is given to the young! and all this is done by foster-mothers—the working bees. The maternal duties of the queens (the real mother bees) extend no further than the production and laying of eggs; and we lately have seen that in this work of production the physical powers of queens are heavily taxed. The industry of bees can never be compassed by man; his highest conceptions fall far short of the reality.

Let us now have a few words on the sagacity of bees. No bee-master need rack his ingenuity to find evidence of the sagacity of bees. It may be noticed in the shape and formation of their cells, which dip or slant downwards. Cells are made for both brood and honey, and of course answer admirably for cradles and store-room. If for breeding purposes merely, they would have been probably made quite horizontal, but if made quite horizontal they would have been more difficult to fill with honey; but the bees have wisely given them a dip, so that they are more easily filled with, and are better receptacles of, honey. If a bit of guide comb be given to bees, with the slant running upwards, they accept the comb but reverse the dip of the cells. See also the ladders used by bees to shorten their journeys indoors. If a swarm put into an empty hive do not nearly fill it, the bees let down two or three ladders or ropes of bees on which the outside workers can more readily ascend to the store-rooms.

What thoughtful care is often manifested by the bees of full hives in cold spring days and nights! At this season bees are instinctively anxious to multiply their numbers as quickly as possible, and set eggs in as many cells as they can cover. If the weather become very cold bees cluster in the doorways, and thus make excellent sandbags to preserve the heat of the hives and save the brood from being chilled. In going to and returning from the fields what ingenuity is displayed in windy weather by bees! They cannot fly against the wind. They will go round the base of a hill, even if it is a mile farther, than over it. In such weather bees seek the shelter of banks and hedges, and may be often seen flying at great speed along open ditches; and when there is no kind of protection to be found, they fly so low that it may be said of them they are kissing the surface as they fly along. The sagacity of bees is sometimes evident when there is a scarcity of flowers in their neighbourhood, or a superabundance of bees for the honey flowers. How frequently have we seen bees disappointed in going from flower to flower in search of honey. They were too late; others had secured the sweets. After trying several flowers without success, we have seen them rise like a rocket and go to another part of the field.

Instances of sagacity may be often witnessed in the preparations made for swarming—in the alterations of their programme—by resolving not to swarm owing to unfavourable symptoms after preparations have been made, also in their attempts at housebreaking and robbery. And what shall we say of bees when they find that their hives and homes are lazar houses of foul brood so unendurable that they abandon them to seek a home elsewhere, and it may be in a strange country?—A. PATTINGRAV.

OUR LETTER BOX.

ENCLOSURE FOR FOWLS (H. C.).—A fence of strained wire netting, large-meshed, 6 feet high, will answer your purpose (if one wing be cut), and effectually confine your hens. The wings may be cut at once, and will not require to be done again till after the next moult. The feathers should be cut down to the quill, but not lower nor into it. You may choose among Spanish, Hamburgs, Houdans, and Crève-Coeur. For ordinary purposes, and for layers only, we prefer the two latter, and of those the last.

DARK EARS OF HAMBURGERS (J. D.).—However good the parents may be in white deaf ears, they will always be some chickens that are inferior, but they will be very few. They fall off in moulting time. They acquire a red tinge if they are much driven about, but we have always found that if we breed from good parents we have had good birds. Our experience of fifty ears is, that a little falling in that respect is often overlooked for the sake of other valuable properties, and the fact is forgotten that defects are not certainly transmitted than virtues.

WOLVERHAMPTON SHOW.—Mr. J. Biddle informs us that his Dark Brahma pullet won the fourth prize.

BARLEYSUGAR FOR BEES (Roselle).—Barleysugar can best be given to bees by thrusting a stick at a time in among the combs at the entrance of the hive. Take care to leave the entrance unblocked by the barleysugar.

QUEEN-REARING.—“J. C. H.” in answer to a correspondent, says that his directions are in Mr. Hunter’s “Manual of Bee-keeping.”

REMARKS.

- 9th.—White frost; fair but very cold all day; less windy towards night; no fog here, but very thick and black in town.
10th.—White frost in morning; fine all day; slight fog between 7 and 8 A.M., but soon cleared off.
11th.—Very dense fog all day, and at times very dark, but the sun was plainly through it, so that it was not cloud, but fog that made it so dark; in London it was fearfully dark.
12th.—Rather foggy early, but a very fine bright day, though very cold.
13th.—Fog, but soon cleared off, a bright pleasant day; snow commenced a little before 7 P.M., and ceased at 9; nearly 8 inches deep all in less than two hours.
14th.—Fine morning, snow still on the ground; a very fine pleasant day, but rain in the evening.
15th.—Rain all the early part of the day; fine afternoon; but rain again in the evening.
A cold week, especially the 11th, on which day the temperature did not rise to freezing even by the sun thermometer.—G. J. SIMONS.

COVENT GARDEN MARKET.—FEBRUARY 14.

PRICES of all kinds of best fruit have an upward tendency, the supply getting shorter. The market is well stocked with early-forced vegetables, the Channel Islands sending good samples of Ashleaf Kidney Potatoes.

From observations taken near London during forty-three years, the average day temperature is the following:—

CULTURE OF CROTONS AND MARANTAS FOR EXHIBITION.

THE first-named genus of ornamental-foliated plants is well adapted for exhibition purposes, and the species best adapted for that purpose are of very easy culture. The staple potting material is good turfy loam from an upland pasture. The turf should be cut thin and stored for about three months before using it. One-third of the compost should be turfy peat, with a little silver sand added, and I have found some broken crocks mixed with the soil to be beneficial. The Crotons require a considerable supply of water during the growing period and a highly moist atmosphere; 70° at night during the summer and autumn months is a suitable temperature. The pots must be well drained: not only is this of the first importance when the plants are repotted, but some of the Crotons peat should be shaken free from soil and carefully placed over the drainage before putting in the compost. I have seen small plants which had been potted in fine soil produce by far the largest proportion of active roots in the drainage.

Crotons are very much a prey to insect pests. The plants must be kept clean, else the beauty of the foliage is marred. Mealy bug is the worst to deal with, and if this gains a footing on *C. angustifolium* the plant is destroyed. Some of the large-leaved species are destroyed by careful washing by hand with soap and water. A spider is another formidable enemy if it is allowed to breed in time. Syringing the plants daily with rain water will keep it in check; but if this is neglected the spider will not increase enough to do harm. The pest is most numerous on the stems and does mischief if not removed by hand-washing. Who has not admired the splendid *C. angustifolium* at the metropolitan exhibition? Its long, narrow, pointed leaves piled one over the other, and drooping down fully until the tips of the leaves touch the ground, as to the colour, one may well quote the words of a poet, describing the doors of the chariot of the sun, "convey home the spirits of the old Scottish bards." They were—

"bright and dazling like gold of the seven stars."

But to obtain the leaves of this bright plant must be placed close to the glass to full bright sunshine. I will name the best adapted for exhibition. Be alluded to above.

C. variegatum is a very good one when well grown; the glaucous leaves set off to advantage the midribs.

C. Wiemannii has proved to be a good one. No. 178—Vol. III.

remain their colour, and the plant is again in its brightest condition.

as well as the old times the result will be seen in the last summer. With the new fruit buds there now, though the days of spring will which appear clean seen swarming with to attempt a cure, still after the flowers are will have received such and curled, and keeping it

insect attacks, as Peaches, the old shreds removed and the walls to which the trees as well as the trees. My plan simple, and I have not yet seen as been described before in your worth repeating. Some fresh-burned little of it put into a tub with some sulphur—about a handful to a quarter ed on the top, and while the lime slakes red, and sulphuret of lime is produced. A less colouring matter is used to produce least objectionable (for mind, it is a fixture the wall, and also on the trees till growth the mixture is left in the consistency of ed for use, when more water is added to make consistency of thick cream. It is then strained h a syringe all over the walls as well as the shreds are of course removed before this, and possible are completely trained afresh; at any rate ed sufficiently to support them.

One will say Peach trees are not pruned till their advanced, and then they will not bear this dress- those who still prefer such late pruning, against and the best teaching, must still go on crippling with the knife at the most critical time, and keep stock of insects to do the rest. My trees of all sorts ed by the middle of January. They ought to be done middle of December, but I am not often able to manage an insect or an insect's egg escapes with its life the I recommend it will be unusual. Standard trees are in the same way. A dozen old Apple trees, infested American blight so badly that the thought of destroying was entertained for a time, were well syringed only once nter with this mixture, and the following season only or four little patches could be found which had escaped. o thoroughly eradicates moss and lichen from the stems; bullfinches, if they are not very hard up, will not touch nds. to not like syringing wall trees daily, as many people do mmer. I fail to see the use of it. It takes up much time n time is valuable, and it often does a great deal of injury

and notes, and not a few expressing surprise that they could not have such highly perfected blooms at home. One lady especially was in trouble at the comparison she was instituting between her plants at home and the noble specimens arranged by Mr. Newton. I took the liberty of speaking to the lady, and to our conversation we soon had quite a little crowd of listeners. I first inquired if she had a large conservatory; to which she replied, "No, but I have a very nice greenhouse with a stage in the centre, and as I am told that these plants have been grown in the open garden all the summer I cannot see why I should not have plants equally fine." "But," I inquired, "have you well examined these plants? because, as plants, I think we cannot call them fine at all. The blooms are splendid, but the plants are—trees." "What! are not these plants fine? Pray explain to me," exclaimed the astonished lady, which I did as nearly as possible in the following words:—

"It is necessary to notice, in the first place, that we are on a platform much higher than the border in which the pots are plunged, and yet, notwithstanding our elevation and their depression, the flowers are higher than our heads; then if we examine carefully we must see that the pots touch each other, and that each plant is but a single stem surmounted by three or four blooms. Now, if we take out a single plant and place it on the walk we find it, as a plant, has no beauty, and the few fine blooms are high over our heads. Suppose, further, we elevate such a plant on your greenhouse stage, how would it look?" "Indeed," interrupted the lady, "I did not think of it before, but such plants would not have room in my house at all; but cannot we have those fine blooms except on tall plants?" I explained that such fine blooms cannot be had otherwise than by limiting their number and growing the plants for a long period without stopping them. Such plants evince skillful culture, but they have had special care, and have been provided for a special purpose.

Now, it is very essential that that be kept in mind. The lady, I take it, represented a hundred others who witness and admire, but who cannot be expected to discriminate in a practical manner and appreciate fully the different circumstances and objects connected with growing plants and flowers for a special and public purpose on the one hand, and those which must be produced for home effect and by home appliances on the other.

Something further may be also kept in mind. The plants produced for public exhibition receive almost the undivided care of an able cultivator. His other duties are subsidiary. He has no hungry cook crying aloud for every delicacy in season and out of season; he has no Grapes which need his care, no Cucumbers to be smitten by disease or Melons with red spider. He has no successional batches of ornamental plants to provide for the conservatory, dinner table, and drawing-room, which must be furnished at all seasons. He has no dinner parties to supply with fruit and vegetables forced and unforced, and a hundred other demands which divide his thought, energies, and attention.

I have often wondered that this matter, which affects so intimately gardeners and their employers, has not had the prominence given to it that the subject demands. Exhibitions are visited, and special results of special effort are submitted for admiration, but seldom are the real facts connected with their production realised. By the accidental meeting with the lady referred to I have no doubt I did a favour to some gardener who was probably doing his best in the discharge of his duties, but who would have had much difficulty in explaining why his blooms of *Chrysanthemums* were not so fine as those which his mistress would have described to him, and produced by plants and under circumstances of which both mistress and man were ignorant. But if I did a favour to the gardener I conferred one also on the lady, who was very glad to be informed on the matter, no doubt as preventing her making a complaint on inadequate grounds.

It may be said in honour of employers generally that they are loth to complain without reason, and that most of them are ready to listen to "extenuating circumstances" when such have real weight. It is to instruct where I think instruction is needed that I pen these remarks, for an object cannot be correctly judged without a full knowledge and appreciation of the ways and means of the producer, and, it may be, the multifarious nature of his duties.

As this is the usual period for commencing preparations for the autumn display, I will append a list of some of the finest varieties that I noticed in London. They were King of Dem-

mark, White Beverley, Prince Alfred, Gloria Mundi, Empress of India, George Glenn, Mrs. G. Rundle, Golden Beverley, Prince of Wales, Pink Perfection, Garibaldi, White Globe, Alfred Salter, Nil Desperandum, Jardin des Plantes (bronze, and yellow), John Salter, Fingal, and White Venus. Those were the finest blooms. I saw also highly attractive plants of the following:—Princess of Teck, Dr. Sharpe, Mrs. Sharpe, Aureum Multiflorum, Aimée Ferrière, Ariadne, Progne (sweet-scented), Lady Talfourd, Prince Alfred, and Julie Lagravère. The best of the Pompons were Asme of Perfection, Miss Julia, Golden Aurora, Antonius, Mr. Aste, Madame Martha, Marie Stuart, Bob, Little Harry, Andromeda, Mr. Dix, and Dick Turpin. In the Japanese section Elaine is the most useful. Gloire de Toulouse, Garnet, Cry Kung, Red Dragon, and The Cossack I also noted as amongst the best.

This may be taken as a useful selection, and if strong cuttings are selected now and not weakened by a high temperature, and if the plants are treated liberally, receiving no checks by being pot-bound or insufficiently watered, a display will be produced next November which will amply reward the grower for his vigilance and attention. I will add further notes on the summer culture of the plants in a future communication.—A COUNTRY GARDENER.

PEARS AND THEIR CULTURE.—No. 2.

OLD Pear trees are often a source of annoyance from the barren state in which they continue year after year. Vigorous shoots are often plentiful enough, and add to our vexation by the clear evidence which they afford that it does not arise from feebleness. Perhaps the worst aspect under which it presents itself is in trees of choice kinds trained to walls. Now wall space is most valuable, and yet it is no uncommon sight to see huge old trees, each spreading its barren branches over 300 or 400 square feet of it. What shall we do with them? It may help to render our answer more distinct if we first of all inquire, What have we done to them? An ardent reformer was once showing me some old Pear trees with magnificent spurs, such as it takes a lifetime to perfect, and describing how he intended "improving" them by cutting away all the old spurs to make them neat, and to have the fruit close to the stems! I was not surprised to hear that the reformer's services were dispensed with after another season. Such instances of foolish mutilation are by no means uncommon. I for one must plead guilty to some blunders in that direction. Spurs are formed solely to obtain fruit; to remove them is to set aside all chances of a crop till fresh spurs are formed, and that crop will be pretty much in proportion to the size of the spurs within certain limits. Let us, therefore, never hastily remove old spurs. If they are crowded thin them, cut away or cleanse any diseased parts as may appear best, manure the soil, and apply liberal surface-dressings to induce a plentiful formation of roots in the upper part of the soil. Give this plan a fair trial, say about three years, and if then fertility does not ensue, waste no more time over the spurs but cut off the branches themselves to within 6 or 8 inches of the main stem, and graft some other sort upon them—a graft to each branch. Such an attempt to renovate old spurs is, of course, only desirable when the variety is of known excellence; in all other instances graft at once. The grafting may be done successfully and with excellent results, even when the stems are in a state of partial decay. I once so grafted a couple of very old trees with perfectly hollow boles. The grafts grew with surprising vigour, forming as fine a lot of fruitful branches as could be wished. Subsequently when the quaint old trees became laden with excellent fruit they were regarded as great curiosities; they certainly were remarkable, as clearly demonstrating by what simple means a recuperation of fertility may be promptly effected.

Orchard trees, whether of a bush, pyramidal, or standard form, are all amenable to this treatment. Whenever you have trees which are unfertile, or varieties which prove unsuitable for your particular soil or climate, never destroy, but cut-back and graft. In doing this it was once customary to remove the entire head of a faulty standard, cutting it back to within a foot or two of the bole. Now we do better by a moderate shortening of the branches, removing all the spray, leaving lengths of 6 feet and upwards, so as to retain all the main and many of the lateral branch stems, using a dozen or two of grafts instead of only three or four, and thus saving all the time which was formerly wasted in reforming the head of each tree, the graft-growth being devoted solely to its legiti-

mate work—the formation of fruiting wood. Bush trees are treated upon the same principle by grafting every main branch after it is shortened to about a foot from the stem. Pyramids also have a graft inserted in every side branch, the form of a cone being retained by leaving the lower branches a foot in length, and graduating upwards to some 3 or 4 inches near the top. The principle which rules the operation in each instance is to retain what may be termed the framework of each tree, regarding the stem and main branches as supports for the fruiting wood, and which, when once formed, should be retained so long as they answer that purpose.—EDWARD LUCKHURST.

LIBONIA FLORIBUNDA CULTURE.

CONSIDERING the time of year at which the above plant blooms, its long duration and easy culture, I think that it is not so extensively grown as it deserves; to promote its more general employment as a decorative plant I will state the mode of culture which I find successful. Cuttings taken at the present time and inserted in good sandy soil will readily strike root in a bottom heat of about 60°. I generally place three or four cuttings in a small pot, and as soon as struck give them a shift without disturbing the ball, as by this means bushy plants are sooner formed than by growing only one plant in a pot. A sandy loam with an admixture of leaf mould is a good compost to grow them in during the early stages of their growth, after which a little decayed manure should be added.

By growing them on in a cool well-ventilated house they are ready to take their stand by the side of *Azaleas*, &c., when the latter are placed out of doors for the summer, the *Libonias* to be treated the same as the *Azaleas*, with the exception of the soil they are grown in. When the time arrives for housing them they will be found to have grown into stiff bushy plants studded with numerous buds, to burst forth ere long into beautiful crimson and orange flowers, which open at a time of year when flowers are generally scarce.

For duration of blooming it is one of the best greenhouse plants, as with tolerable attention it may be kept in flower from December to March, producing a good effect when placed amongst *Deutzias*, *Coronillas*, &c. It is also useful for cutting from for bouquets, and is generally admired by ladies.

After the blooming season is over the plants may be shifted, or, if convenience requires, only the surface soil may be removed and replaced by a rich compost, and the pots placed in an airy part of the greenhouse until the time comes round to remove them out of doors again. They require a good deal of water, and especially during their growing season should not be allowed to get dry, or a shedding of the lower leaves is the consequence.—W. W.

LEEKS.

CAMBRIA may have adopted for its emblem the Leek for its usefulness and to spite its neighbouring kingdoms. Anglia had adopted the Rose, Scotia the spiny dreathed Thistle, and Hibernia the lowly mystic Shamrock. The Rose emblematic of the beautiful, the Thistle of resistance, and the Shamrock of dependance, all lack the representative utility expressed by the Leek. Leek is not a greatly favoured article of Welsh vegetable diet, and is not cultivated by the possessors of gardens, in small or large plots, as are Gooseberries by the Lancastrians or Celery by the Sheffield cutlers. It is not in Wales or among the Welsh that the Leek finds its votaries. It is not until we advance to and even pass the "border" northward that we find extended and careful culture given the Leek, and where it is valued at its worth as an ingredient of soups, stews, &c. There the occupier of, it may be, but a rod of ground brings to bear upon his Leek trenches so much skill and enthusiasm as to attain a result shaming that of those of vastly higher pretensions.

In Leek culture size is the all-important object sought—a stout stem well blanched. This can only be attained by high culture, affording rich soil and very liberal treatment during growth. The practice of some is to raise their plants in gentle heat as for Celery, and transplant to well-manured trenches, and dose frequently with manure water, and blanch with soil as for Celery. This plan answers well; but I find a result almost if not quite equal at a considerable lessened entail of labour, by sowing the seed the first open weather in March in drills 18 inches apart on ground that has been trenched and heavily manured in autumn, and thrown-up roughly for the

winter, and thrown level in February, giving a dressing of well-decayed manure and wood ashes, pointing-in a few days prior to sowing. Some fine wood ashes are sprinkled in the drills after sowing, and the seeds are sown rather thinly. Hoeing is practised to keep down weeds, and the plants are thinned to 8 inches apart, and then to 6 inches, leaving the strongest each time, and every other plant is removed as required for soup, the plants being left 1 foot apart in the rows, and after May liquid manure is poured between the rows, blanching being effected by ashes, sawdust, or cocoa refuse. For general purposes I sow in rows 15 inches apart, thin to 6 inches apart, take out every other plant as required through the summer, and do not blanch.

Henry's Prize Leek has been looked upon hitherto as the finest sort, it and Aytton Castle Giant having probably still the longest and cleanest stem; but Carentan last year had a stem twice the thickness but shorter, appearing a giant Musselburgh, and as like in growth as two Leeks not having the same name can be, and this is probably the best kind for general purposes.—A. G.

WAR WITH INSECTS.—No. 2.

Now is the time to wage war with outdoor insects as well as those inside, while they are comparatively scarce and not very active. Wait another month and it will take three times the amount of labour to exterminate them, while the result will be less satisfactory. Depend upon it, their head quarters are not far from the places which they visited last summer. Crannies of walls, old shreds, and spaces between fruit buds and branches are favourite winter resorts for them. With the aid of a microscope they may be seen there now, though perhaps quite inactive; but a few sunny days of spring will bring them out in strong force, and trees which appear clean and healthy one day may the next day be seen swarming with red spider and aphid. It is too late then to attempt a cure, for no strong measures can be taken till after the flowers are set, and by that time the new foliage will have received such injury that it will remain crippled and curled, and keeping it clean then is out of the question.

Trees which are very subject to insect attacks, as Peaches, and the like, should always have the old shreds removed and burned, or at least scalded, and the walls to which the trees are trained should be dressed as well as the trees. My plan for dressing them is very simple, and I have not yet seen anything so effectual. It has been described before in your columns, but perhaps it is worth repeating. Some fresh-burned lime is procured, and a little of it put into a tub with some warm water; a little sulphur—about a handful to a quarter peck of lime—is sprinkled on the top, and while the lime slakes the sulphur is dissolved, and sulphuret of lime is produced. Soot or other harmless colouring matter is used to produce the colour which is least objectionable (for mind, it is a fixture when it gets on to the wall, and also on the trees till growth removes it), and the mixture is left in the consistency of mortar till required for use, when more water is added to make it about the consistency of thick cream. It is then strained and applied with a syringe all over the walls as well as the trees. All old shreds are of course removed before this, and the trees if possible are completely trained afresh; at any rate they are nailed sufficiently to support them.

But someone will say Peach trees are not pruned till their buds are far advanced, and then they will not bear this dressing. Well, those who still prefer such late pruning, against all reason and the best teaching, must still go on crippling their trees with the knife at the most critical time, and keep up their stock of insects to do the rest. My trees of all sorts are pruned by the middle of January. They ought to be done by the middle of December, but I am not often able to manage it. If an insect or an insect's egg escapes with its life the dressing I recommend it will be unusual. Standard trees are dressed in the same way. A dozen old Apple trees, infested with American blight so badly that the thought of destroying them was entertained for a time, were well syringed only once in winter with this mixture, and the following season only three or four little patches could be found which had escaped. It also thoroughly eradicates moss and lichen from the stems; and bullfinches, if they are not very hard up, will not touch the buds.

I do not like syringing wall trees daily, as many people do in summer. I fail to see the use of it. It takes up much time when time is valuable, and it often does a great deal of injury

to the trees, especially on the afternoon of fine bright days when the walls have been heated to a great temperature by the sun. The water is always colder than the walls, and the rapid evaporation and consequent chill produced must be very injurious to the trees. I suppose the only thing that can be said for it is that it knocks off insects, and perhaps some of them may be hurt by the fall. A much better plan, in my opinion, is to syringe once or twice during the growing season with water in which soft soap has been dissolved, about two ounces to a gallon. This should be done in the evening after the sun is off; then it will not harm the trees any more than clear water would, and it will prevent insects attacking them. Soft-soap water is also an effectual cure for mildew on Peach trees, much more so than sulphur.

The syringe, although a very useful instrument when properly used, I believe does a great deal more harm than it does good in the hands of the unskilful, while many who are not unskilful use it far too much indoors as well as out. At the time of closing a forcing house on a hot bright day, when evaporation has been excessive, the syringe is invaluable for dewing over the foliage of plants and moistening the atmosphere of the house, so as to check evaporation for a time till the plants recoup themselves; but the house should be perfectly closed first. The water should always be a little warmer than the house, and should be applied to the plants in the form of fine spray only, for hard syringing will injure all tender plants.

Syringing in dull weather is not required, the comparative low night temperature that most successful growers now maintain does away with the necessity for it, for when the temperature rises naturally in the morning a natural dew is also produced, far better than any syringing can do it.

The syringe is fondly believed in by most people for encouraging Vines and other plants to break regularly and freely. This is a delusion; I have proved repeatedly that it makes no difference at all to them. I never syringe Vines at all, nor forced Peach trees till after the flowers are set, when they are occasionally dewed over at closing time. What is the use of painting Vines, &c., over to kill insects, and then immediately wash the mixture off with a syringe? The regular starting of Vines depends on the wood being ripe, the roots comfortable, and a comparatively low temperature.—Wm. TAYLOR.

HARDY CYCLAMENS.

I AM much obliged to "R. C." for his remarks on Cyclamens, but I think much yet requires explanation. I have a hardy white-flowering one, which blooms every year most profusely about August without any foliage, and like "R. C." I have sometimes surrounded it with leaf mould in the hope that it might bury its seed vessels and send up a batch of seedlings, but I have never been able to obtain any, although the greenhouse species that we plant out upon a sunny border the latter end of April or beginning of May seeds and reproduces itself most abundantly. Whether it is by the hardy species blooming too late for the seed ripening or not I cannot say, but I partly suspect the young seedlings fall a prey to slugs, which abound very much where the plants are grown. Yet we know that the Cyclamen hederifolium is a native of this country, and as such reproduces itself in the usual way; but unquestionably it has its favourite nooks and corners. I remember once on visiting a garden of some note in Cornwall, being shown an edging to a walk in the kitchen garden of Cyclamens that were just putting forth their leaves. This was about the 1st of September, and I understood they had been established there some years. I think they were the same kind that is grown in greenhouses elsewhere, but this is not the hardy one I inquire after.

Might I ask if there is in reality more than one hardy species, and if so will someone describe where they respectively bloom? If the hardy species I have alluded to could be induced to produce seedlings, and these be taken up and potted at the time they are in flower, few plants could be more attractive in August, excelling as it does its more tender species in the multitude of its blooms. Cutting a large bulb or corm into pieces and planting them out in sandy soil is only an uncertain way of increase, so many of the "sets" not growing; but I yet hope to see the Cyclamen as plentiful as the Primrose, if the right way to manage it were only understood.

The greenhouse one was many years an inhabitant of the shelves of that structure, without being regarded as anything

more than a botanical specimen, until the last ten years or so has brought it out into the prominent position it now occupies; and cannot something of the kind be done for the hardy species? As I said before, I am yet in doubt about there being really more than one hardy species and one tender one, but the great diversity of form which the latter has taken, and the countries from which it was imported, has led to more names being given to it than are required. This, I think, is all but generally acknowledged by botanists, and if so, what do they say about the hardy species? Will someone be pleased to describe to us the one from the other, and the proper name for each?—J. R.

OLD TREES—PRUNING GOOSEBERRY BUSHES.

I HAVE this week seen a tree that I backheaded three years since; in this case, a Jargonelle Pear on a wall. I had not much faith that it would ever make a good tree again, for it was much cankered, but it has quite succeeded. It has made plenty of healthy wood, and although there are no fruit buds visible there are many promising-looking spurs. I may add that I cut each branch off about 18 inches from the main trunk.

And now I wish to say a few words about Gooseberry trees. Many men who call themselves gardeners seem to have no idea of keeping a full-sized tree to a convenient height, except by cutting all young wood down within an inch or two of the base. I took charge of a plantation that had been pruned or rather clipped on that system. There was no fruit on the bushes, and I was told there had not been any worth mentioning for years. My employer told me to uproot them and plant young bushes, but I begged to be allowed to try them one year myself. I shall never forget what a job I had with those trees the next winter. They were crowded with short dead bits and strong young shoots. I left some of the young wood, shortening the shoots about two-thirds, and all the rest I clipped off, not cut. The following summer a lady came on a visit. She looked round the garden, and then came to me and said, "Well, gardener, I have been here every summer for fifteen years, but I never saw such crops before, especially of Gooseberries." And truly their burden was greater than they could bear. Why should so many try to grow a few big Gooseberries? If they would aim at a medium size and large quantity they would give and find more satisfaction.

In conclusion, I do not believe in anything in the way of shears for pruning Gooseberry trees, whether they be called *sécateurs*, or what are termed here guillottes, which are supposed to give a clean cut but in reality do nothing of the sort. They are often spoken of as being more expeditious than a knife, but I can do more work with a good knife and a strong pair of leather gloves, and I am certain the work will be better done than by clipping.—J. J., Lancashire.

DALECHAMPIA BOEZLIANA BOSEA.

FLORIFY of propagation, easy culture, free blooming (even when the plants are only a few inches high) during the winter months, long endurance of the flowers in beauty, and delicate sweetness, are some of the recommendations of this plant. It is, however, as well to say that the flower is a lump of yellow disposed at the internal base of the two large rosy pink bracts which guard it, and it is on these floral bracts that the beauty of the flower depends. It has besides the fine floral bracts alluded to, which it produces from the axil of every leaf, rather long, deep green, wavy, oak-like foliage, which hangs down so as to cover the stem. Altogether this is a very easily cultivated and desirable stove plant. It seeds very freely, and requires to be watched when approaching ripeness, as the capsules burst and the seeds are distantly distributed. Wherever falling they are certain to grow, and the plants come up with me in sea gravel, in tan, and in the soil of pots containing other plants, and is simply a stove weed.

The seeds should be sown at the present time in a hotbed, and the seedlings potted-off singly into 3-inch pots when they are large enough to handle. The plants should be grown-on in brick moist heat, and be kept near the glass with a moderate amount of air. They usually commence flowering in January, and will continue to do so for some time. The plants should be shifted into 4½-inch pots when they have filled the 3-inch pots with roots; but I keep some in the 3-inch pots, as I find these plants very useful. A compost of turfy loam, with a third of leaf soil and a little old cow dung, grows them well. They

require to have the soil always moist and to be freely watered during growth and flowering, evidently refreshing a syringing twice daily, morning and evening.

The plants will continue to grow and flower for a number of years, requiring only to be potted in the spring of each year. I have plants now of nearly seven years' growth which are kept in a free-flowering state in 7-inch pots, the old soil being removed at each potting, so that the plants may be returned to the same size of pot. Weak liquid manure twice a week invigorates the foliage and flowers.

If the flowers be removed after they fade (the capsules fall so as to be hid amid the foliage), and the plants be kept from seeding, their flowering will be much enhanced. The rosy pink bracts of this plant make neat button-hole flowers.—G. A.

NOTES AND GLEANINGS.

A NOTE ON MR. ORMSON'S ESTABLISHMENT at Stanley Bridge, Chelsea, will not be inappropriate. The place is historical as well as horticultural and commercial. Mr. Ormson's residence was once in part the mansion of King Charles. The bole of the tree is preserved which that Monarch is said to have planted. The front of the "Royal" residence which was once the garden is in some sort a garden still, being occupied by glass structures of various designs, such as the roof conservatory, curvilinear (straight glass) portable vinery, span-roof and lean-to houses. The garden "decorations" consist of boilers in every conceivable shape and size—saddles, simple, divisional, corrugated, convoluted, perforated, and arterial; there are also conicals, pyramids, Trenthams, and tubulars. Mr. Ormson has been "getting-up heat" for more than a quarter of a century, and has instituted many improvements in hot-water engineering, the latest being the patent tubular Cornish boiler, the patent divisional hot-water apparatus, and the patent arctic hot-water stove, designed for ships and schools.

—AN excellent specimen of *ODONTOGLOSSUM ALEXANDRE* is now flowering in the stove at Wimbledon House. The plant has thirty-three expanded blooms on three spikes and is very beautiful. There is also an unusual form of *Antirrhinum Scherzerianum*, the flower having a double or twin spathe, the spathe being single. We have observed before that healthy specimens of the "Fleming" Plant have occasionally perfected a "pair" of "wings."

—MR. FOULIS, gardener to G. H. Henderson, Esq., Ffordell, Fifeshire, has been awarded the NEEL PRIZE, value £54, for his abilities as a gardener and geologist. The prize is the triennial interest of £500 left by the late Patrick Neil, Esq., to be awarded by the Royal Caledonian Horticultural Society to some distinguished botanist or horticulturist. Mr. Foulis is to be congratulated on the honour which he has won.

—WE hear a rumour—which we think not unlikely to strengthen into a more certain sound—that the scheme for REMOVING THE OXFORD BOTANIC GARDEN from its present historical and picturesque site to the bleak and arid "parks" has fallen through, and that immediate steps are to be taken to put the existing establishment on an efficient footing.—(Nature.)

—WE are informed that *LAPAGERIA BOHEA* is hardy in Cornwall, and that it has been seen covering a wall having a north-west aspect. It would be interesting to hear if experiments have been made testing the hardness of this fine climber.

—THE King of the Belgians is erecting at a cost of £80,000 a GRAND WINTER GARDEN at Laeken. The structure is of imposing dimensions, the roof being 120 feet in height in order that tall trees may have room for development.

—FOR EXTERMINATING MEALY BUG, writes a correspondent in the *Rural New Yorker*, I have never found anything so good as alcohol, or even common high-proof whisky will do. With a small soft brush one can soon clean the bugs from a hundred plants, no matter how badly infested. Dip the brush into the alcohol, and then let a drop or two fall upon a cluster of mealy bugs, and they will disappear. There are some very delicate kinds of plants which the alcohol will injure if used too freely; but there is not much danger in its application to the ordinary kinds cultivated in greenhouses.

—*TAMARIX PLUMOSA*.—Nothing can be finer or more graceful than this species, which is still so rare in spite of the readiness with which it can be propagated. Its numerous

slender branchlets of a glaucous green hue bear a certain resemblance to the curled plumes of the ostrich (or the white stork), whence its popular name of "Marsh-stork." It flowers in August about the same time as *T. indica*. The flowers, which are disposed in dense erect panicles, have an airy lightness, which adds much to the elegance of the foliage. Isolated on a lawn or in a large park *T. plumosa* forms a compact mass of the most pleasing appearance. It is quite as hardy as *T. indica*, and propagated and treated in precisely the same manner.—(Revue Horticole.)

—A CORRESPONDENT in the *English Mechanic* recommends the following mode for making TARRED WALKS:—First gravel the walk in the ordinary way, but do not give it so thick a coat as usual; beat well down to make a perfectly smooth and even surface, which coat well with tar. When this is done put the final layer of gravel on the top—three-quarters of an inch to 1 inch will be quite sufficient, and again beat down, using the back of a spade for the purpose. The walk so prepared must not be trodden upon for two or three days, at the end of which time it will have become perfectly hard, and will not be affected by the heaviest fall of rain. The work must be done in fine weather, and the plan will be found better than using cement mixed with the gravel.

—MR. DUNSTAN, Coroner, at the Parkside Asylum, Macclesfield, has been investigating a case of poisoning of an unusual nature. A patient, Emma Linnell, died apparently in an epileptic fit. A *post-mortem* examination was held, resulting in finding in the stomach of deceased some green fluid, also Holly seed and fragments of Holly, Laurel, and Yew leaves in quantities sufficient to cause death, and a verdict was returned in accordance with the evidence.

—THE HORTICULTURAL HALL, at the approaching Centennial Exhibition to be held at Philadelphia, is an imposing structure, with a length of 383 feet, and width of main building 193 feet. Its height is 72 feet to the skylight. The Centennial Conservatory, 280 by 80 feet and 55 feet high, occupies the main floor, and in this the exhibition will be made. On the north and south sides of the principal room will be the forcing and propagating houses, each 100 by 80 feet, covered with a curved roof of glass and iron. Similar vestibules occupy the east and west ends, and by the side of these are rooms for offices, &c. Ornamented stairways lead to the interior and exterior galleries of the conservatories. These latter are 10 feet wide. The entrances at the east and west ends will be approached by flights of blue marble steps. The basement is fire-proof and used for storehouses, cool room, kitchen, and heating apartments. The entire building will be mainly of iron and glass, and is intended to remain after the Exposition as an ornament to Fairmount Park and a patriotic memorial of the first Centennial Celebration of Horticultural Progress.

—A CORRESPONDENT in the American "Gardener's Monthly" says, "You will be doing many a poor fellow a great kindness if you will again warn and keep warning against the fatal mistake of painting hot-water pipes in greenhouses with GAS TAR." We have lately had brought to our notice an instance of a nurseryman near London, who tarred the stage of a large plant house to the great and probably irreparable injury of many valuable plants which were afterwards wintered in the house.

—HARDENING PAPER.—The French papers speak of a method of rendering paper extremely hard and tenacious, by subjecting the pulp to the action of chloride of zinc. After it has been treated with the chloride it is submitted to a strong pressure, thereafter becoming as hard as wood and as tough as leather. The material may be employed in covering floors with advantage, and an excellent use for it is large sheets of roofing. Paper already manufactured acquires the same consistency when plunged unsized in a solution of the chloride, and is useful for many protective purposes.

THE ARRANGEMENTS OF COLOURS

IN THE BEDS OF THE LONDON PARKS AND GARDENS.—No. 7.

EXAMPLES having been given of suitable modes of effectively planting circular beds, a few designs suitable for beds of an oval form may appropriately follow. Round beds are the most common of all forms; they are also adaptable to an almost endless variety of modes of planting them, and if the plants are judiciously selected, and their colours correctly arranged, few, if any, forms of bed show to better advantage.

The plans which have been submitted are sufficiently numerous to meet various tastes, and also as embracing or providing for the employment of the several plants which are usually prepared for this mode of decoration.

Oval-shaped beds are less numerous than round beds, but are equally effective when properly planted. Two suitable

and free bushy-growing plant, having silvery grey foliage. Its erect habit of growth makes it desirable for lines in mixed beds. It is propagated from seeds or cuttings in autumn or spring; the autumn cuttings strike freely in a cold frame or under a hand-glass. In spring it is best to place the plants in a little heat, and then the shoots that are made will strike freely.

Fig. 36.—Bed K.

and distinct modes of planting an oval-shaped bed are now figured; they are quite different in character, and have an agreeable appearance. Three other plans of planting beds of this shape will follow, which will afford ample choice for intending planters.

BED K.

1. *Geranium Robert Fish*.—This is a very dwarf and compact variety; the foliage is pale yellow, the flowers bright

4. *Alternanthera amabilis latifolia* (orange and red).—A bold, strong-growing, and showy variety, enduring alike in rain or sunshine. It may be used in any exposed situation, and will maintain its bold and dense character until late in the autumn. Last season it remained in perfection in Hyde Park until November. It is a superb plant for designs, and it may be used in other ways with great advantage.

5. *Lobelia Blue Stone*. 6. Silver variegated *Geranium*.

Fig. 37.—Bed L.

scarlet. It is a free bloomer, distinct, and beautiful, and very effective for lines in ornamental beds.

2. *Cineraria maritima compacta*.

3. *Achyrocyline Saundersonii*.—This is a very distinct, neat,

7. *Echeveria secunda glauca*. 8. *Stellaria graminea aurea*.

BED L.

1. *Golden Pyrethrum*. 2. *Alternanthera amosa*.

3. *Helichrysum maritimum*.—This is a comparatively new

plant, and is excellent for a margin to a bed of dwarf plants. The small leaves are glossy and shine like grey satin. It is a creeping plant, forming itself into a neat and compact border. It is one of the most desirable and effective plants we have for edgings. It propagates itself, and will keep well in a cold frame.—N. COLLE, *Kensington*.

OUR BORDER FLOWERS—DAME'S VIOLET OR ROCKET.

A RACE of plants consisting of annuals, biennials, and perennials, some of them having found their way to our shores from the continent of Europe and other countries hundreds of years ago, and in all probability occupied prominent places in our borders in days gone by, before the rage for novelty had set in. One of these is enumerated as a native of our own land, but I doubt its claim to nationality; at all events we have it, and a right welcome guest it is.

Hesperis matronalis in the spring and summer time is a worthy occupant of our shrubby borders, by the margins of ponds, in wilderness scenery and out-of-the-way corners, and when once established it only requires to be left alone to take care of itself. In sheltered nooks it gives us in the spring a good addition to the bouquet, its pleasing perfume being always acceptable to our sense of smell, and is one of its greatest attractions. Glowing colours are attractive, but when combined with delicious perfume they become doubly interesting. Then we have the double *Hesperis matronalis* in several varieties, often taxing the cultivator's skill to the very utmost to keep-up a stock of flowering plants. It is useless attempting their cultivation if we do not make-up our minds to succeed with those gems of our borders. Perseverance must be our motto and success our aim. We must be prepared for disappointment too.

I find it good practice to have plants in reserve in a rather shady and moist but not a wet situation, not suffering them to bloom when stock is required, and dividing them when they have made moderate growth. They should have efficient drainage under all circumstances, and be supplied with water as they require it. They should be carefully watched when they are making their growth, for belonging to the Brassicae tribe they are often attacked by what is known as the Turnip fly, this pest often destroying the young growth by eating-out the heart of the plant. A good sound loam with thoroughly decomposed manure, charcoal dust, and a little coarse sand will meet their requirements. In an open border, and if left to themselves, they are but short-lived, often requiring renewing. In some places it is almost impossible to succeed with them, but when their requirements are supplied they become more manageable. When at their best no plants are more attractive, none more esteemed than our old-fashioned Rocket, or, as some call it, "Evening Star"—and stars the flowers are. Prizes ought to be offered at horticultural exhibitions for collections of those neglected flowers.

They are increased by cuttings and division. When the best of the bloom is past the stems should be partially cut-down to encourage growth. When they have made moderate growth divide in autumn, potting or planting the divisions as may be desired. When the flower stems rise they should be secured from being injured by the wind.—VERITAS.

ROAD-MAKING.—No. 2.

In continuation of the subject of road-making alluded to on page 83, it may be stated that where the ground is impervious to water means ought to be taken to make the foundation as dry as possible, which can only be done by putting in plenty of drains and insuring their having good outlets. These drains need not necessarily be deep. Many years ago, in making a carriage road through a piece of stiff ground a very slight excavation only was made, but it was depressed in the middle, both sides sloping down to the centre, and a tile drain was inserted there about 18 inches below the surface where the two slopes met. This 18 inches was filled with rough stones; the foundation of the road was pared smooth, and kept so by not allowing the wheels to touch it until it was covered with stones, and thus a very good road was made. In like manner a larger space may be done in the same way by the ground being formed into a series of ridges and furrows with drains in the latter—that is, where more especial care is required to lay the ground dry.

Although the above is likely to be effectual, it is a good practice to roughly pave the bottom of the road before the

small stones are laid on, which is best done when rough, flat, irregular-shaped stones abound—say, in pieces 8 or 10 inches across and 3 or 4 inches thick. The surface ground being ready, these stones ought to be placed by hand closely adjoining each other and on their edges, leaving the upper surface as rough and irregular as possible, as this unevenness helps to catch hold of the loose small stones that follow, while the paving, if it may be so called, acts as an additional drainage. The bottom stones may be soft if necessary; in fact I am not sure but that sandy stones are best. They are always expected to be below the action of the wheels, and consequently only serve to keep the road dry. It is always best to insure good workmanship at the first, disturbing a road afterwards never ought to be necessary. Either of the plans described above, or it may be both of them, had better be adopted where the case seems to call for it. Provision for gas and sanitary drains ought always to be thought of when a road is being made. If the basement stones are packed on their edges rather than merely tumbled in out of the cart or barrow, the after material adheres better to them, and there is no likelihood of their getting loose and finding their way to the top, which large stones are liable to do when merely mixed with small stones, and especially when the surface-coating of broken stones is a thin one.

Besides stiff clayey ground alluded to above there is another kind still more difficult to manage, and that is the peat moss. I recollect a piece of such road that used to vibrate very perceptibly when a heavy load passed over it, and yet the road was a good one: its foundation no doubt rested on a good covering of Gorse, Heath, or bushes, which was the usual way such difficulties were met. I have on more than one occasion had recourse to these substances to form a bottom in a very wet place, and it is surprising the saving there is in stone; besides which the road is unquestionably better, and there is no likelihood of materials so buried decaying in any very early time and letting the road through. I have seen a piece of road altered that was known to have been built on Thorns, Brambles, &c., and at the expiration of nearly ninety years only the smaller twigs were decayed. The road-maker of the present day who has any particularly wet or dirty place to encounter cannot do better than cover it first with Gorse, Heath, bushes, or branches of any kind, and over them he may lay the stones. I remember once having a particularly soft place to encounter, and the soft watery mud seemed determined to make its way up through a moderate layer of nice short Gorse that was carefully laid over it all in one way; but when we gave it a covering of the same substance in a contrary direction it stopped the propensity the soft spongy matter had to rise and a very good road was made; but of course where it is practicable it is better to drain all such places.

The above being about the worst place to form roads upon, let us take a glance where the object is attained with the least trouble and expense. We shall find that in some dry stony districts a road is about half formed already to our hand, and it requires but little labour to complete it, the natural dryness and hardness of the bed being such as to require few stones to make a really good road. Sand is a bad foundation, and ought to be made dry first of all; but there are dry sands that cannot be excelled by anything, and I am not very sure but a builder would as soon select a good dry sand on which to erect a castle or a church as any other foundation he could have. Sand of this nature makes a dry road, perhaps too much so, as rounded gravel is unwilling to bind upon it. Clays of some kind or other are the most common, and if divested of all superfluous water will carry a good road, the great matter being both to drain the bottom well and to arrange that no water stands on the top. The latter is best guarded against by the quality of the material used in the road and the prevention of overhanging trees. Plantations and high hedges on each side exercise a hurtful influence on roads. This work, like most other operations, is governed by *£ s. d.*, and the expenditure need not be very great if the work be gone about in the right way.—J. KOBSON.

SOIL FOR RHODODENDRONS.

My experience is that these handsome shrubs will not thrive where the soil is shallow and overlying limestone or any other rocks. They need the steady uprising moisture of the earth, which rocks impede. They delight in vegetable matter, and grow well in the loam of woods, but will not do so in that of open fields. I allude to a limestone district. I have planted them in nearly all sorts of soil—clay, sand, loam, and peat in

old woods and plantations—and they have grown as freely as any other shrubs or trees, and much more freely than most, for rabbits must be hungry indeed before they will eat *Rhododendrons*. But they have failed to grow in the ordinary soil of the garden, first because it was deficient in decaying vegetable matter, and secondly because of the dryness of the subsoil.

In sandy loam and having a moist base *Rhododendrons* grow perfectly. In the vicinity of Manchester, for instance, few shrubs flourish so well as do these. They will grow also in clay, but are slower in becoming established than in lighter soil. They are susceptible of great injury by digging amongst the roots; and after planting them, no implement working deeper than the hoe should be used amongst them. I am convinced that that and a moist base is of more importance than the staple character of the soil.

In the gardens lately in my charge, situated in a dry limestone district, *Rhododendrons* could not be made to flourish except by deep excavations and introducing vegetable matter, peat being preferable, but in the woods and plantations on the same estate they are growing by hundreds in peat, loam, and clay. In my opinion they are moisture-loving plants and will not thrive well on a dry subsoil, let the surface soil be of whatever nature it may.

With a moist base and deep soil, whether of loam or peat, I should not hesitate to plant these shrubs freely, and by not digging amongst them I should expect them to flourish, but I have never seen them grow freely in shallow soil on a substratum of limestone.—A FORESTER.

PERENNIAL ASTERS.

ASTERS are capable and worthy of a much more liberal and scientific treatment than even the best that can be done for them with the spade. The *Phlox*, when treated in the rough and ready way in which *Asters* generally are, is but a sorry decorative plant as compared with that which is grown from a cutting annually and cultivated with some liberality; and so with *Asters*, which are susceptible of exactly the same treatment. A single cutting of an *Aster* struck in a mild hotbed in spring, may be made a much more beautiful object in the autumn than a considerable clump of the same with its multitude of stems tied up as they usually are to a single stake, with no better result than that of strangling the development of a large number of them. Some sorts are better adapted for being grown single-stemmed than others, but all the late-blooming sorts are improved by being annually raised by cuttings. Those that have the finest effect when grown in this way are such as develop their inflorescence in pyramidal form and which branch freely from the lower part of the stem upwards, those blooming only on the upper part of the stem in paniculate or corymbose style being less elegant; yet for certain positions, such as where they are designed to overtop masses of low-growing shrubs with their bloom, they are most desirable. In the herbaceous border, where every plant is, or should be, seen apart from its neighbours, the pyramidal sorts are extremely elegant and beautiful; so much so, that I strongly urge a trial of the method on all who desire to have the best of everything in its season. The treatment of the cuttings is precisely the same as is given to cuttings of *Phloxes*, with this difference, that they are more easily spoiled by heat, and should therefore never be coddled up in any way. They must be planted out as soon as they are thoroughly well established, the ground being previously well dug and manured if poor. One plant only, or three or four, may be planted together according to degree of massiveness and bulk desired; and should they throw up any suckers or stems from the root, these should be removed at once so as to concentrate the whole vigour of the plant on the development of one stem. Support the stem properly as it advances in growth. The following list comprehends twenty of the best sorts for decorative purposes, and the earliest and latest bloomers.

A. alpinus.—A neat, compact, dwarf plant, growing about 9 inches high, best adapted to rockwork, and for the front line of a mixed border. The flowers are solitary, very large and bright, but rather pale purplish blue, opening from May till August. Native of mountain pastures on the Alps and Pyrenees. There is rather a beautiful but rather rare white-flowered form of this plant that is very desirable.

A. altaicus.—This is also a dwarf-growing species, with very large bright mauve-coloured flowers, blooming very freely in July. Native of the Altai mountains.

A. concolor.—Another dwarf neat-growing sort, with simple

erect stems, terminating in raceme of deep purple flowers at the height of a foot or 18 inches. It blooms continuously from August to November. Native of North America.

A. discolor.—A very neat and effective sort, growing about 18 inches high. The flowers open white, and change to pink or reddish purple, and are produced in corymbs on the upper part of the stems. They appear in August and September. Native of North America.

A. amellus.—This species grows about 2 feet high, with erect rigid stems, generally unbranched till near the top, where they break out into an open corymb of pale blue flowers, which appear in August, September, and October. Native of Central and Southern Europe.

A. blandus.—This species grows from 2 to 3 feet high, with the stems numerous branched in pyramidal style, bearing a profusion of pale purple flowers in October and November.

A. dumosus.—An upright-growing sort, with stiff freely-branching stems, furnished almost from the base to the apex in pyramid shape. The flowers are produced in the greatest profusion, and are white, but small, opening in September and October. Native of North America.

A. elegans.—This sort grows about 2 feet high, branching gracefully and freely. The flowers are produced very abundantly from August till October, and are bright purplish blue. Native of Siberia.

A. ericoides.—One of the most elegant of the group when properly managed as to staking, &c. It grows about 3 feet high, branching most freely from the base upwards. The flowers are small individually, but in the extreme profusion in which they are produced they are most effective. The colour is white, and they open in September and October, and in northern places last till November.

A. grandiflorus.—This species grows about 3 feet high, and branches freely in pyramidal fashion. The flowers are deep blue or purple, and open in October and November. The flowers are large and fine, but the late period at which they open renders it a plant ill-suited for northern or cold late places, except when a position at the base of a wall with a southern exposure can be devoted to it. Native of North America.

A. levis.—A handsome bright blue-flowered species, growing about 2 feet high. The flowers are produced in corymbs, and open in September and October. Native of North America.

A. longifolius-formosus.—A remarkably beautiful sort, growing about 2 to 3 feet high, with fine bright rosy-red flowers. The species *longifolius* is a comparatively uninteresting one with whitish flowers in no way comparable with this variety, which is one of the most ornamental and pleasing of *Asters*.

A. Nova-Angliae.—One of the handsomest and most effective of *Asters* as regards its flowers and inflorescence, but rather too tall and weak in the stem to be considered tidy and pleasing in habit. The stems rise to the height of 4 or 5 feet, terminating in large open panicles of bright violet-purple flowers which appear in September, October, and November. There is a very fine and distinct form of this species named *ruber*, which has the flowers, as the name implies, red—a fine bright red—which in other respects is identical with the purple-flowered species. Native of North America.

A. Novi-Belgii.—This grows about the same height as the last, but the flowers are rather smaller, and pale blue with a conspicuous yellow disc. The flowers appear in September and October. Native of North America.

A. puniceus.—This species grows about 3 feet high, with stout stems terminating in an open corymb of purple flowers, which open in September, October, and November. Native of North America.

A. paniculatus.—A fine large-flowered species, rising to the height of about 4 feet, the stems branching freely at the top, and forming an open panicle of bright blue flowers, which open in October and November. Native of North America.

A. patens.—A dwarf-growing species, about 18 inches high. The flowers are produced in open panicles, are deep purple, and appear in September and October. Native of N. America.

A. sericeus.—A very distinct and pretty species, with somewhat stubby stems branching freely, each branch terminating in a solitary large fine blue flower. It grows about 3 feet high, and flowers in summer and autumn, and into winter in warm localities. Perhaps not hardy in the north of Scotland, where I have had no experience of it. Native of Missouri.

A. turbinellus.—A very handsome species, growing to the height of from 3 to 4 feet. It branches freely and flowers very profusely. The flowers are large, fine dark blue or

purple, opening in September and October. Native of North America.

A. undulatus.—This species grows from 3 to 4 feet high, branching abundantly. The flowers are very profuse, pale blue, and open in August, September, and October. Native of North America.—W. S.—(*The Gardener*.)

MILDEW AND RED SPIDER SUBDUED.

MR DOUGLAS asks what is to be done if red spider appears on the Vines, for if you put sulphur on the pipes he is afraid the fruit would be rusted. Now what I have to impart is not new, but is not so well known as it should be. It answers no good purpose to paint the pipes with sulphur, but the reverse. It is sulphureted vapour in the atmosphere which we want to destroy both red spider and mildew; dry sulphur does no harm to either.

If at the time of closing the house Mr. Douglas will place a pail half filled with cold water in the vinery or any other house affected with spider or mildew, and take half a pound of sulphur and mix it up in a basin with boiling water till it is quite made into a paste, then mix it in the pail with the water, then place in the mixture some lumps of unslacked lime, he will create a vapour that will destroy both red spider and mildew without injuring the most tender plant. If the house is a large one two pails will be better than one. In the morning the spiders will be found dead in their webs, or if not, the vapour has not been strong enough; but in any case it will be well to repeat the dose a few nights after to destroy the offspring that were in the eggs at the time of the first operation. I keep the unslacked lime on the boiler, for if not kept dry it will go down and be of no use.

For thirty-six years I have not been troubled with spider or mildew on my Peach walls, but both pests had been very troublesome to my predecessor. After the trees have been nailed I mix 6 lbs. of sulphur and tone it down with soot and apply it on the wall with the syringe or engine. I put it on thickest at the bottom of the wall for the vapour from the sulphur to ascend amongst the foliage. After the fruit is set, on a fine sunny afternoon when the wall is still warm, I syringe with milkwarm water; the vapour will spread itself over the whole wall. I do this two or three times a week on fine days. Syringing the tender foliage of Peach trees with cold water is a sad mistake, too often practised I am sorry to say.—J. C., Felton Park Gardens.

HISTORY OF THE LUCOMBE OAK.

[We have been favoured with a copy of a letter from John Zephaniah Holwell, Esq., F.R.S., dated from Exeter, February 22nd, 1773.]

SIR,—In my rambles through this city I have been tempted to visit the nursery of Mr. W. Lucombe, of St. Thomas, on the report of a very extraordinary and new species of Oak, first discovered and propagated by that ingenious gardener; and as this plant appears to me capable of proving an inestimable acquisition to this kingdom, I cannot resist the desire I feel of communicating to you some particulars relative to its history and character.

About seven years past Mr. Lucombe sowed a parcel of acorns, saved from a tree of his own growth, of the iron or wainscot species. When they came up he observed one amongst them that kept its leaves throughout the winter. Struck with the phenomenon, he cherished and paid particular attention to it, and propagated by grafting some thousands from it, which I had the pleasure of seeing eight days ago in high flourishing beauty and verdure, notwithstanding the severity of the winter. Its growth is straight and handsome as Fir, its leaves evergreen, and the wood is thought by the best judges in hardness and strength to exceed all other Oak. He makes but one shoot in the year—viz., in May, and continues growing without interruption; whereas other Oaks shoot twice—viz., in May and August. But the peculiar and inestimable part of its character is the amazing quickness of its growth, which I imagine may be attributed, in some degree at least, to its making but one shoot in the year; for I believe that all trees which shoot twice are for some time at a standstill before they make the second. I had the curiosity to take the dimensions of the parent tree (seven years old) and some of the grafts: the first measured 21 feet high and full 20 inches in the girth; a graft of four years old 16 feet high and full 14 inches in the girth. The first he grafted is six years old, and he outshot his

parent 2 feet in height. The parent tree seems to promise acorns soon, as it blossoms and forms strong footstalks, and the cup upon the footstalk with the appearance of the acorn, which with a little more age will swell to perfection.

This Oak is distinguished in this country by the title of the Lucombe Oak. Its shoots in general are from 4 to 5 feet every year, so that it will in the space of thirty or forty years outgrow in altitude the common Oak of a hundred years of age. I have a leaping pole full 5 feet long, a side shoot from one of the graft only a year and a half old. From the similarity of this Oak to those of the iron or wainscot Oak it appears to be a descendant from that species, though it differs from it in every other particular. Several gentlemen around this neighbourhood and in the adjoining counties of Cornwall and Somerset have planted them, and they are found to flourish in all soils.

PORTRAITS OF PLANTS, FLOWERS, AND FRUIT.

CROCUS WELDNERI. *Nat. ord.*, Iridaceæ. *Linn.*, Triandria Monogynia.—“This can scarcely be considered as more than a variety of *Crocus biflorus*, with which it agrees in time of flowering, leaves, and corm-structure. The flower is less showy than those of either the old garden *biflorus* or the two wild Italian varieties (*lineatus* and *pusillus*), being entirely without stripes, concolorous at the throat, and white, except that the three outer segments are marked on the outside with a more or less decided hue of slaty-purple. It is a native of the limestone hills of Dalmatia, flowering in January and February. In our English gardens it does not expand till March.”—(*Bot. Mag.*, t. 6211.)

STAPELIA OLIVACEA. *Nat. ord.*, Asclepiadaceæ. *Linn.*, Pentandria Digynia.—“This interesting species appears to have been known for some little time in gardens as *Stapelia eruciformis*, although there seems to be some doubt whether that name does not belong to another species (*Gardeners' Chronicle*, 1875, iii., p. 206). It was sent to Kew by H.E. Sir Henry Barkly in April, 1874, where it flowered in September following.”—(*Ibid.*, t. 6212.)

CYPPELLA PERUVIANA. *Nat. ord.*, Iridaceæ. *Linn.*, Monadelphia Triandria.—“This handsome Irid, new so far as I can make out, was introduced in 1874, by Messrs. Veitch, from the Peruvian Andes. It does not agree with the six species of *Cypella* described by Klatt in his monograph above cited either in habit or precisely in stigma. They are all natives of Brazil, and have spathe produced from the sides of great ensiform Iris-like leaves. Here the habit is substantially that of *Phalocallis*, *Polia*, or *Beatonia*, but in all these the stigmas are materially different. These South American Irids are very difficult to study, the flowers being so fugacious in a living state, and seldom represented in a satisfactory manner in herbarium specimens. We have in the Kew Herbarium specimens of either the same plant or a closely allied one from the temperate region of the Bolivian Andes, in grassy places, near Sorata, gathered by Mandon.”—(*Ibid.*, t. 6213.)

PESCAITORIA DAYANA var. *RHODACEA*. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—“In the present state of Orchidology it is not possible for the botanist or the horticulturist to speak with confidence of generic limits in any considerable group. I have retained this under *Pescatoria*, following Reichenbach (in the *Gardeners' Chronicle*, l. c.), by whom the genus (usually wrongly written *Pesatorea*), was founded. As above observed, however, this genus has been referred by him to *Zygopetalum* as long ago as 1861, together with *Bolles*, *Warszewiczella*, *Warrea*, *Kersterinia*, and *Promenæa*.

“*Pescatoria Dayana* has several varieties in cultivation, depending on the markings on the perianth being absent, or violet, or green, or red. That here figured was communicated by Messrs. Veitch in September, 1874, and a perfectly similar plant, but without red tips to the sepals, was sent by Mr. Bull the previous June.”—(*Ibid.*, t. 6214.)

VIBURNUM DILATATUM. *Nat. ord.*, Caprifoliaceæ. *Linn.*, Pentandria Digynia.—“A very handsome hardy shrub, with apparently a wide distribution in Japan, having been collected in various localities from Nagasaki and Yokohama to Hakodadi—that is, nearly throughout the length of the archipelago.

“*V. dilatatum* was introduced by Messrs. Veitch, who sent flowering specimens for figuring to Kew in June last, with the information that it is perfectly hardy.”—(*Ibid.*, t. 6215.)

SENECIO (KLEINIA) CHORDIFOLIA. *Nat. ord.*, Compositæ. *Linn.*, Syngenesia Superflua.—“A very curious succulent Groundsel, remarkable for the great length of its simple,

terete, cylindrical leaves, which droop from the long, slender branches, and for the lax, slender, very few-flowered cymes. It is one of Mr. Cooper's South African discoveries; he found it at Bughersdorp, in the Albert province, in 1861. It flowered at Kew in July, 1874. The specimen was presented by Mr. Kennedy."—(*Ibid.*, t. 6216.)

PEAR—Pitmaston Duchess.—"Originally this Pear was called Pitmaston Duchesse d'Angoulême, and it is figured under this name in the *Gardeners' Chronicle* (1864, 1108), where it is described by Mr. Robert Thompson. We, however, follow Dr. Hogg in abbreviating the name to Pitmaston Duchess, which is more distinctive, as, though a seedling from Duchesse d'Angoulême, it bears no resemblance to that variety. The tree, as we learn from Mr. Cramb, 'is of a vigorous habit, particularly when grafted on the Pear stock, and so fruitful as scarcely ever to miss a crop even during unfavourable seasons, whether grown as a bush, or pyramid, or standard. The fruit is generally in use from the beginning to the end of October, varying a little according to the season. The average weight is from 10 ozs. to 12 ozs., and for exhibition purposes it has few, if any, equals. The flavour is excellent, not quite so sugary as many of our autumn sorts, but still first-class; the flesh is in a high degree melting, very juicy, and perfumed. No collection should be without this desirable Pear, did it possess no other good quality than that of having a fine appearance.' The Pear was raised by the late John Williams, Esq., of Pitmaston, in 1841, and is a cross between the Duchesse d'Angoulême and Glou Morceau; he further refers to it as a very handsome and most excellent variety, and adds, 'few of the new Pears can compare with it as regards size, appearance, and quality; it partakes more of the nature of Marie Louise than of the Glou Morceau.' The fruit is described as 'very large, oblong obovate; the stalk short, obliquely attached, projecting more on one side than the other; the eye in a moderate-sized depression, the segments of the calyx erect and projecting to the level of the fruit; skin soft, smooth, yellow, with slight thin russet near the stalk. Flesh yellowish-white, exceedingly melting, buttery, very juicy, and rich.' Its remarkably tender, melting flesh, and its rich sprightly flavour and delicate perfume, are qualities in which it is excelled by few of our large-fruited varieties of Pear. Mr. Scott, who calls it Williams' Duchesse d'Angoulême, remarks that it is a noble fruit, the largest melting Pear known to him, and certainly one of the finest. He adds that it grows freely on the Quince, on which it fruited with him in 1869, on a tree two years old, and the next year, 1870, was in full flower again on trees 3 feet high."—(*Florist and Pomologist*, 3 s., ix. 37.)

ARTIFICIAL ROCKWORK.

MR. PULHAM has called me to task for my remarks about artificial rockeries. To tell the truth, I rather expected to have had my remarks criticised before this, but I do not think Mr. Pulham has at all shaken me from my position. No artificial rockery that I have ever seen has the least resemblance to Nature, least of all concrete and stucco with sham stratification. Use boulders and stones as large as ever you can procure them, and pile them up to resemble cliffs as much as possible, so as to obtain variety and massiveness, but it is utterly bad taste and cockneyfied in my opinion to try and pretend that it is a natural rock by joining the boulders together with stucco and cement, and marking out lines of stratification. No one is ever deceived by it. I know I may differ from the authorities Mr. Pulham mentions, but still I venture to do so, as I still maintain that where Ferns and alpine plants do best is among the disintegrated rocks and alpine boulders, and that it is a great chance if any one of these stones are found on their natural bed.

One of the best instances of rockeries I know is at Mr. Backhouse's at York, and though there are boulders and rocks and artificial water, yet there is no attempt to put every stone on its right bed, or to make believe that it is a natural stratified rock pushed through contrary to Nature. Of course I quite agree with Mr. Pulham, if it is wise to imitate a natural cliff it is right to put all the stones on their proper beds. I think Mr. Ingram's spring garden and rockeries quite perfect in their way, but think he is unnecessarily cramping his energies when he is using large flat stones, and arranging them artificially and unnaturally, to think it necessary to lay each flat on its bed in the original position in which it lay in the strata, for in the natural dolls formed by the disintegration of rock, and which is the nearest approach in Nature to such a garden

as that at Belvoir, the stones would not be found in their natural beds.

No doubt on the ledges and crevices of sandstone cliffs many Ferns and wild plants will grow, but it is generally in the disintegrated soil, and not on or in the stratified rock; and certainly if we want to see Ferns growing to perfection it is amongst the huge boulders and smaller detritus and stones at the feet of lofty cliffs, and by the sides of streams and water-courses, such as one sees in so many parts of Switzerland and the Italian Alps, and in a smaller way in Scotland and the rocky hills of Yorkshire.

My remarks, however, against artificial rockwork were chiefly directed against the concrete and plaster and stucco imitations, which are neither imposing in themselves nor do they impose on the public, and are certainly not adapted for the growth either of Ferns or Alpines. Nothing is worse taste in my mind than broken clinkers, distorted and misshapen bricks, spar, oyster shells, *et id genus omne*. The only legitimate materials to use in rockwork are stones, whether large or small: the larger and more diversified they are in form, so long as there are plenty of smaller pieces used and a sufficiency of soil, the better. Rockwork does not want to be an attempt to deceive, but a picturesque place to grow Ferns and Alpines.—O. P. PEACH.

RHODODENDRON ARGENTEUM VAR.

WE do not know to which of the Indian Rhododendrons introduced and flowered in these countries the title of king has been accorded, but we certainly venture to regard the noble *R. argenteum* as their queen. It unquestionably must be regarded as at least being among the cream of Dr. Hooker's Rhododendron discoveries in the Sikkim Himalaya. Quite a tree, attaining in its native country a height of 80 feet or more, with its large, and in part, silvery foliage, it must present a noble aspect, especially so in the spring, when the new leaf buds are forming, the latter having the appearance of rosy-coloured cones. But what must be its aspect when its branches are crowned with its glorious flower heads?

We are induced to allude to it thus prominently on the present occasion by reason of seeing recently in flower at Glasnevin what we cannot help regarding as a very fine variety of this magnificent species. Among the other choice plants just then in flower in the cool conservatory there were two large specimens of *R. argenteum*, both being pretty much about the same age and size. In respect of the flower and flower heads the disparity was very striking, as on one plant they were far larger and finer than the other. The smaller we should be inclined to regard as the normal form, for it seems to agree better with the figure in Dr. Hooker's magnificent book embodying his discoveries. The gorgeous flower heads are very large, as are also the individual flowers. The head is formed of several tiers of flowers, each resting horizontally on the one below. The flowers are pink in the bud, but as they expand become white. Each flower shows at the bottom of the great open tube a rich dark purple spot encircling the base of the stamens; this is very conspicuous by reason of the way the flowers present themselves to a front view. The cluster of anthers with their purple stamens add much also to the effect, but of all the floral organs the stigma is the most striking, on account of its great size and bright rosy carmine colour. This, we may remark, is not shown in Dr. Hooker's or any other figure of it we have seen, as in no case is the large stigma shown as it is in nature—brilliantly and strikingly coloured. Mere word-painting altogether fails fitly to describe the soft voluptuous beauty of these glorious flower heads, more especially as displayed in the larger and very fine variety which has been for the last week or two the glory of the house in which it stands. Both forms, we gathered from Dr. Moore, were raised from seed. There were, moreover, several other choice Indian Rhododendrons in flower in the same house, and among them one which, as regards symmetrical compact heads and fiery brilliancy of colour, has no equal—namely, *R. barbatum*.—(*Irish Farmers' Gazette*.)

NEW BOOK.

Picturesque Europe—The British Isles. Cassell, Petter, and Galpin, London. Part I

WE make this an exception to our rule not to criticise a serial publication until completed, because we wish to aid in promoting the sale of a work which we strongly commend to

our readers as one of the most beautiful we know, whether we refer to the type, the paper, or the views. The information imparted by the Editor is interesting and popularly written. The work judiciously commences with Windsor, and its first pages relate to the Castle.

The garden attached to the Castle is not worthy of such a palace; the chief attractions of its grounds are the terraces and the trees of the parks. The elevated position of the Castle enables most extensive views to be commanded over these from its windows. One of the most attractive of those views, looking towards Eton, being from the library window, a favourite one of the late Prince Consort, is shown in the woodcut accompanying these notes. For this illustration we are indebted to "Picturesque Europe."

Heartily do we wish that it was permissible to trace the history of Windsor Castle from Roman times to the present. We could fill a page with notes on the coins of Constantine and Probus found in its vicinity; and then of the origin of Windsor forest, made by William the Conqueror, and protected by a characteristic law that "hares should go free, and whoever killed a hart or hind should be blinded," an effectual mode of preventing the poacher repeating the offence.

A vineyard was appended to the Castle, and the vintager's pay first commences in the Pipe Rolls for 1155. Lambard records

"that tythe hathe bene payed of wyne pressed out of Grapes that grewe in the Little Parke theare, to the Abbot of Wal-
tham, and that accompts have bene made of the charges of planting the Vines that grewe in the saide parke." Richard III. in the first year of his reign appointed John Piers to be "Master of our Vynearde of Vynes of our Castell of Wyndesore, and otherwise called the office of Keeper of our Gardyne called the Vynearde." He and his deputy were to have as

"wages and fees sixpence by the day." The garden, however, down to the close of Henry VIII.'s reign did not receive the care, nor did it cover a space equal to others of the Royal gardens. The wages of the gardener at Windsor were only

£4 a-year, but those of the gardener at Beaulieu were more than £12. The gardens at Greenwich, Richmond, and Hampton Court are shown by the privy purse accounts to have chiefly furnished the King's table with fruits and vegetables.

In the year 1272, Henry III. being King, there was issued an order for timber "to pale and enclose the garden;" a fountain of freestone and a well were also constructed in it. But Edward III. let on a long lease "the garden plott" to the Corporation of Windsor, and the lease was renewed by subsequent monarchs until about the year 1700. It was rather more than three acres, and is described as "a gardine and orchard bricke walled round." King James I. of Scotland, who was confined for some years as prisoner in Windsor Castle early in the fifteenth century, gives us in a poetical effusion a description of its garden, which similarly intimates to us that it was of contracted space and formal adornments:—

Now was there made
fast by the touris
wall
A garden faire, and in
the corneris set
An herbere grene, with
wandis long and
small
Rallit about, and so
with trees set
Was all the place, and
Hawthorn hedges
knet,

That lye was now, walking there for by
That myght within scarce any wight espye,
So thick the bewis and the leves grene
Beschudit all, the allyes all that there were,
And myddis every herbere might be sene
The sharpe green swete Jenepere,
Growing so fair with branches here and there,
That as it semyt to a lye without,
The bewis spred the herbere all about.

Another garden in the reign of Edward III. is described as

Fig. 88.—WINDSOR CASTLE—VIEW FROM THE LIBRARY WINDOW.

being "without the Castle," and its gardener's weekly pay was "twopence halfpenny."

We shall at a future season publish some notes on the present gardening at Windsor Castle.

HEATING SMALL GREENHOUSES.

Of late years some enterprising firms in obedience to the demands for small greenhouses, forcing houses, plant-protectors, &c., suitable for amateurs of limited means, have obligingly advertised these structures, giving full dimensions with the cost of the whole including the necessary staging and pathway. All these improvements have come about within the last twelve or fifteen years, and many of your readers will know how to appreciate their value. At the time I mention, the erecting of a small greenhouse was a much more troublesome affair than at present, being attended with so many disappointments. One certainly might ascertain the cost of the greenhouse itself, and possibly decide to have one if his means would permit, but when it was brought home he found out that what he innocently supposed to be part and parcel of the structure—viz., the staging and shelving, had been overlooked in the estimate by the practical builder, and the unpractical amateur had to dip his hand further into his already shrunken pocket to pay for these indispensable extras—a little particular that might possibly have deterred him from making the attempt to possess a greenhouse at all had the builder put him in possession of all the facts at the start. But happily this is no longer the case. One can now know exactly what the cost will be, delivered at the nearest railway station.

But now commence the troubles of the modern amateur. He can know from the advertising columns of "our Journal" what the cost of a house will be, of any dimensions that his means will permit him to adopt. But what he cannot discover from the same source is, how much it will cost him to heat it effectually with hot water pipes.

Now, if it pays horticultural builders to advertise—and it must do, or the advertisements would not continue to appear—full and exact particulars of the prices of the article they deal in, it surely would pay the horticultural engineer to do the same. The builder tells us he will supply a structure from 10 feet by 7 or 8 feet, to any length, width, or height we wish to have at a given cost, and delivered complete ready for work. This is definite and satisfactory. Giving the engineer credit for as much enterprise as the builder, one would naturally expect him to follow suit, and advertise that he would heat these structures of given dimensions for so much, either to adapt them for cool greenhouses or to enable their purchasers to grow winter Cucumbers in them; in fact, to use them as forcing houses, stating the price in full. They, of course, know how many feet and sizes of pipe are necessary to heat a given length of house for a given purpose, also the kind of boiler (either gas or fuel) sufficient to do the work in a fairly satisfactory manner. Let them state these particulars, and people can then choose for themselves, without going to the trouble of writing for estimates. It is not enough to say that a boiler can be had from 50s. to 60s. upwards. This is no information at all for the uninitiated. It is even of little use if it were stated how many feet of pipe it would heat. What the amateur wants to know is how much pipe and what boiler will heat a house of a certain size, and how much it will cost him. Certainly plain and reasonable questions. This is written solely in the interest of amateurs in horticulture—a very numerous class, and for whose sake I should be very glad to see my suggestions carried out as far as is practicable.—T. L. C.

YOUNG VERSUS OLD TREES.

MUCH as has been said of late in favour of old trees, more especially of old forest trees; something is also due on the other side, for I have known many a leaning to old favourites carried too far, and an after-generation had just cause to complain. Even an old-tree hobby may be ridden too hard, as when a too great liking to trees forbids their being duly and timely thinned; the issue is then the reverse of creditable, and the good appearance of the trees is irretrievably gone, especially if they be of the Pinus tribe. Deciduous trees will struggle, and in some measure come round a little, but Firs never do so: hence the propriety of timely thinning them in plantations where a well-furnished bottom is the object. Offences of omission are quite as common as those of commission in the management of ornamental timber trees, not that I am an

advocate for much pruning—the less, in fact, the better; but judicious and timely thinning of young growing trees is as much a duty as the cutting of the old trees is a fault.

I should like to see young trees planted more freely. Many proprietors of domains feel a just pride in their noble trees, but would seem to forget that they have only a limited existence. Trees which give importance to parks and grounds cannot last for ever, yet but little is done to replace them. Where the space hardly allows of a greater number of trees than already exists, I would not hesitate to advise the taking-away now and then of an old worn-out tree where it can be dispensed with without injury to the general effect, and replacing it with a young one; not, of course, in the same spot, but somewhere in the grounds where it may seem wanted. I fear there are many parks and estates in which there is a lack of trees of from ten to twenty or thirty years of age, while very old trees are plentiful enough.

I sometimes think the rule or law said to exist in Japan, that for every tree that is cut down there must be another planted, might well be acted upon here. One cannot but regret the worship of utilitarianism which is frequently exhibited by those who fell trees freely but plant them reluctantly. Be assured there will come a day in which the fine old trees which are now so much prized will no longer fulfil their offices, and the proprietors of the present day will be reproached by the generation then in occupation for not planting trees at the proper time, forgetting, or possibly not guessing that it was respect for the trees now in existence that prevented it being done. I hope, therefore, that the cry, "O spare the tree," may not be carried too far, but that even a little sacrifice of present appearance may, if necessary, be made, and a few old trees, favourites though they be, might be cut down to be replaced by young trees that will be wanted many long years hence. As we have inherited much in this respect from our ancestors, is it not reasonable that we should bequeath something in turn to those who will come after us, by occasionally planting a few trees?

In performing the proper thinning or cutting-down of old to make way for young trees some judgment is, of course, necessary, or mistakes may be made. Plantations of Scotch or Spruce Fir that have stood unthinned for a number of years must be very sparingly thinned at first, and not at all, or but very little, on the windward side, and especially if in a very exposed position. I remember some years ago seeing an example, showing the evil effects of not adhering to this, on a plantation crowning one of the heights of a chalk hill in Surrey. Someone had advised an opening to be made to obtain a view to some place of eminence in the distance, which was done the required width; but the wind rushed in and increased the width of that opening in a frightfully ugly manner, clearing whole rods of ground of the trees, much to the mortification of the proprietor. I believe it was many years before the remaining trees regained anything like a decent condition. Such accidents or mistakes are not uncommon, and I mention this to prevent others of a like kind occurring. My final advice is to thin plantations judiciously and provide for the failure of old by planting young trees, or some parks will in a few years be denuded of timber.—J. ROBSON.

CHAPTERS ON INSECTS FOR GARDENERS.

No. 6.

My last communication closed with some remarks on midges, introducing also to the gardener the familiar insects known as gnats. I may appropriately refer to their history and habits; for gnats also, like the midges, are visitants to gardens—not merely visitants in some instances, since they are often born and bred within the garden precincts. In many suburban gardens it is customary to collect rain water and store it in tubs and tanks; or in other gardens, rain water not being handy, river or well water is kept until it becomes soft. These receptacles, if uncovered, are sought out by female gnats, which have a liking for still water; and I have heard gardeners blamed for having (unconsciously) gnat-nurseries on their premises, thus multiplying our tormentors in the summer season. But then, again, people have argued that a few square yards of water in or close to a garden are of utility, serving to drown a good number of insects both by day and by night.

The singular life history of the larva of the common gnat has been already referred to in this journal, and it may serve as a sample of the economy of the Culicidæ. The feathery palpi and antennæ, and the proboscis extended in front, enable

ordinary observers to recognise gnats with little difficulty; though a majority are not awake to the fact that the non-plumed female, less often seen, is the only gnat that is felt and also heard, for the shrill cry preceding onslaught is only produced by the female insect. According to Prof. Westwood the proboscis or beak of the gnat, small as it is, represents all the complicated parts discernible in the largest insect, and his admirable description runs thus—"There is a broad and hollow lancet-like piece, representing the upper lip; a pair of slender needle-like pieces, serving as mandibles, serrated on the outside at the tip; a second pair of similar but much more slender organs dilated at the base, representing the maxillæ; a very slender needle-like instrument, representing the tongue; and then there is an outer tubular canal in which these parts lodge when at rest, representing the lower lip."

Persons engaged in gardens are much exposed to the punctures of these pertinacious blood-suckers, and it may be worth recording that as good an application as any to relieve the irritation is arnica lotion not too weak. Undoubtedly by some means or other the insect, when drawing blood, injects poison into the wound, to render the blood more fluid it is thought: hence some Americans strenuously advise people to allow gnats to finish their repast, urging that when they do so they remove the poison with the last draught. One more comment on these Oulioidea ere we dismiss them. Did it ever occur to any reader how strong a gnat must be? You may have seen on some flower bed a tortoiseshell butterfly or a sphinx moth poised on expanded wings and remaining apparently motionless in the air, and you have wondered how it's done. Gnats can do the same thing and keep it up for hours—rising and falling, it is true, yet not yielding an inch of air, as Mr. Staveley says; hovering steadily, exactly in the same perpendicular. This is accomplished by means of a series of band-like muscles which cross and recross the thorax, which may be seen by the microscope. The centre of gravity also falls in this part of the body through its proportionate stoutness, which is an additional aid to this sustained hovering.

Two small families, not very noticeable, serve as a connecting link between the gnats and the crane flies. First the Phlebotomidae, which, though so named, contains species that are harmless enough, such as the tiny dirty grey insect which shows itself in houses and conservatories on mild winter days, crawling or hopping on glass or woodwork. Entomologists call it *Psychoda phalenoides*, and its odd springs or hops are performed by the help of the sloping wings, which are very downy. The larva or maggot lives in manure. Amongst the Heteroliteæ are aquatic as well as terrestrial larvæ. The hind margin of the wings will be found to be fringed with hairs on these flies, not with the delicate scales occurring amongst the gnats.

Lastly, as belonging to the Nemocera section of the Diptera, I have to name the Tipulidae, lanky-legged creatures, which one associates more with the later summer or autumn than with any other season of the year. These flies are at once distinguished from all the families already noticed by a transverse seam which crosses the middle segment of the thorax. To some people the readiness, or seeming indifference, with which a daddy-longlegs parts with one or more of these useful limbs is matter of surprise. Clumsy as we may think these insects in various situations where they occasionally attract our notice, they are not awkward when skimming among the grass or low herbage, for which pursuit they are admirably formed. A few species have aquatic larvæ, but the bulk of them feed underground, on roots chiefly, haunting lawns and fields, occasionally also the kitchen garden. *Tipula oleracea* is a well-known pest, rejoicing in the vague name of "wire-worm;" but this and other species are well held in check by numerous bird enemies.—J. E. S. O.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

THE weather has lately been very unsuitable for out-of-doors operations; but as soon as the ground is in a friable condition all spare ground will be cropped, except what is intended for successional crops of Peas, Beans, &c. When the ground is sufficiently dry it ought to be lightly forked over. Hitherto all the Peas have been sown on borders well exposed to the sun, but we shall now sow Dr. Hogg, Fillbasket, and G.F. Wilson in the open garden quarters. This last-named sort may be only an early selection of that famous Pea Veitch's Perfection; if it is, it is earlier and quite as prolific. We are much indebted to those who carefully select from a good stock, but it is doubtful

if they ought to give a new name to the variety they have improved, as it tends to confusion. With this sowing Spinach will be sown between the rows.

Mice and sparrows are well known to be troublesome. Red-leading the seeds, placing sand in the drills, or cutting furze into short lengths and strowing it over the Peas in the drills before filling-in the soil, has been recommended to prevent the attacks of mice. This may be worth trying, but we set traps as soon as there is any trace of mice. They go to the traps, and the Peas are saved while the enemy is destroyed. Where there are such clouds of sparrows as we have, it is little use running strings over the rows or placing any object to scare the birds; Pea-guards made of galvanised wire netting bent over the rows are most effectual. When the young plants reach the netting it is removed to the next sowing, and the rows from which the netting has been removed are earthed-up and sticks placed to them; after this they are seldom touched by the sparrows. If we could have glass covers similar to the protectors it would be a great advantage for the first crop.

It is no use sowing Dwarf Kidney Beans out of doors until all danger of their being destroyed by frost is over; but if a sowing could now be made in a pit or frame the produce would come in useful about the end of May, and the plants would yield gatherings until they could be obtained from the first sowing out of doors. We have not yet planted out our early Potatoes; they are much better in the boxes in the cool orchard house; they are placed one layer thick, with some cocoa-nut fibre refuse over them enough to cover the tubers.

Parsnips have been sown in ground that had been well trenched. We sow the Hollow-crowned; a good stock of this is the best for all purposes. The Parsnip is one of the most easily cultivated vegetables we have; it thrives in any soil, but the ground should be well trenched and manured. For the preceding crop the rows are 18 inches apart, and the plants are thinned to 8 inches apart in the rows. The roots keep best in the ground during winter, but a portion should be lifted and stored where they can be reached easily, if the weather is such that the roots cannot be lifted out of doors.

Carrots and Onions will also be sown if the weather continue favourable. The Onion delights in rich manure being dug into the ground, but not so the Carrot; and it is better to crop on ground that has been well manured for a previous crop, or place the manure about a foot below the surface. We had some ground deeply trenched and manured in this way; the soil that was dug up from the bottom being placed on the surface, taking care to have all the surface soil at the bottom. On this ground a crop of sound Carrots was obtained quite free from the maggot, whereas in previous seasons the crop was worthless. We found the maggot again attacked the crop when the ground was trenched next season. The spring-sown Onion crop also suffers severely from the maggot, which causes us to sow in autumn and transplant in spring.

A good plan to insure early Onions is to plant small bulbs at once. The ground should be forked over, and the small Onions planted in rows just deep enough to cover the top of the Onion. When the seedstalks appear break them off. This will cause fresh bulbs to form, which will be in use much earlier than autumn-sown seeds.

The best Carrots are Early Short Horn and Jamee's Intermediate. The Altringham is good for a general crop. Of Onions White Spanish and Brown Globe are amongst the best. Leeks must be sown at once to be planted out when they are sufficiently advanced. Shallots and Potato Onions are best planted in the autumn, but if that has not been done the operation should not be delayed longer. Autumn planting prevents the attack of maggots. The Welsh Onion, which does not form bulbs, should also be sown in the autumn. This is a hardy species from Siberia of strong flavour. Garlic is not much used for culinary purposes; it ought now to be planted in light dry soils; the bulbs, of course, are divided into single sets, or, as they are termed, "cloves;" these are just covered over the top. And lastly we would mention Chives. These are easily cultivated, and are useful in the spring for salads and soups. The plant is perennial, and will continue to throw up leaves for two or three years, when the clumps must be taken up and be subdivided, replanting again on fresh ground. It makes a good edging plant for a border; the leaves only are used by being cut over close to the ground.

PINES.

Some of the plants intended to fruit in the house that was started about the 1st of January seem to make too rapid growth to show fruit. We have had such plants that would grow until midsummer before any fruit showed. The plan of cutting the plants over close to the surface of the ground is well known now to Pine-growers. The plants should be operated upon as soon as it is perceived that they will not show for fruit; 9 or 10-inch pots are sufficiently large in which to pot. Some five or six of the largest leaves should be removed from the base, the compost should be rammed-in rather firmly, and water must not be applied for at least a week. The suckers that were potted into

7-inch pots early in the autumn ought now to be repotted, but this operation must be delayed until we can find room for them. When the Pines are repotted is a good chance to turn the tan in the bed; and if this is spent, and fresh tan cannot be obtained, the old material may be sifted, reserving the rougher portion that remains in the sieve to mix with the fresh tan. This turning and mixing the tan in the bed will raise the temperature very much, which is just what is required to promote root-action. When the roots are matted round the insides of the pots is the time that danger is to be feared from overmuch bottom heat. 70° at night with a rise of 15° by day from sun heat is a good temperature for them at present.

PLANT STOVE AND ORCHID HOUSES.

The weather is very mild at present, and with but little artificial heat the night temperature is sometimes up to 70°. It is also necessary to use the shade on bright sunny days. As nearly all the plants are starting into active growth an increase of moisture is necessary in the atmosphere as well as a higher temperature. We have been repotting *Nepenthes* and *Sarracenia*. The last-named, being an American genus, may be considered quite as much a greenhouse as a stove plant; but the plants do better in a cool Orchid house than they do in the greenhouse. A rather close moist atmosphere is that best adapted to them. The pots are filled to one-third of their depth with clean drainage; over this some sphagnum moss is placed to keep the drainage clean, and the compost, which is composed of very fibrous peat and sphagnum in equal parts; a few bits of charcoal and some potsherds are added to it. All the genus *Nepenthes* require similar treatment to the *Sarracenia*. It is very undesirable to injure the roots. The outer surface of the ball when it is turned out of the pot may be full of roots. If it is thought desirable to reduce the ball it must be done by carefully picking out the old compost with a pointed stick. The copious supplies of water that this class of plants requires causes the compost to become sour, and if this should be the case it is certain that the old material must be removed. The potting material must be pressed in only moderately firmly with the fingers. The plants must also be shaded from sunshine; in fact a house with a north aspect is the best in which to grow *Sarracenia*. Mr. Baines used to grow his magnificent specimens in a cool fernery. A few of the best *Sarracenia* are *S. flava* major, *S. Drummondii*, *S. purpurea*, and *S. variolalis*; these are distinct in character. Of *Nepenthes* may be named *N. Rafflesiana*, *N. phyllamphora*, *N. Hookeriana*, *N. levis*; and last may be named the rare, and beautiful as rare, *N. sanguinea*.

We have also put in cuttings of some softwooded plants to flower in the autumn and winter. Of these are the *Bouvardias*. The most useful for cutting from is *B. Vreelandii*, *B. Hogarthii*, and *B. longiflora*. *Eranthemum pulchellum*, the blue flowers of which are charmingly distinct, harmonise well with *Bouvardias*. *Thyracanthus rutilans* makes famous flowering specimens from cuttings struck now, and the lovely *Monochæmum ensiferum* does well with similar treatment. *Ixoras*, *Gardenias*, *Hoyas*, *Torenia asiatica*, *Plumbago rosea*, *Pentas carnea*, and *Medinilla magnifica* will strike well now in bottom heat, and will supply the place of larger plants that it may be necessary to dispose of from their growing too large for the house. *Ixoras* and *Gardenias* strike best with a bell-glass over the cuttings. This should be wiped inside daily with a dry cloth.

FLOWER GARDEN.

We continue to put in cuttings of *Verbenas*, *Coleus Verschaffeltii*, *Ageratums*, &c. All these rapid-growing bedding plants are much better to be propagated from cuttings in the spring, even if there should be a sufficient stock of autumn-propagated plants. If the later-rooted plants may be much smaller at planting-out time than those that have been kept over the winter they will grow away more freely, and by midsummer will make the best flower beds. Bedding *Calceolarias* are now in boxes in cold frames, but if the frames are wanted for more tender subjects the present occupants will be planted out in trenches similar to those for *Celery* plants. Our *Lobelia speciosa* was sown early in autumn, and has been pricked out into boxes some time ago. Spring-sown plants do not come into flower sufficiently early.

Dahlia roots must be put into heat at once. The tubers may be planted thickly in a box in light soil, and the label may be fastened to the old stem to insure correctness. The buds will soon start into growth either in a hotbed or forcing house, the latter to be preferred. Hollyhocks may either be propagated by cuttings or by root-grafting. They may be planted singly in small pots, and the pots plunged in a gentle bottom heat. They do best in a heated propagating house, as they sometimes damp-off in a cold frame.—J. DOUGLAS.

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

LIVERPOOL (Spring Show). March 5th. Mr. R. Wilson Ker, 6, Bassett Street, Church Street, Hon. Sec.

LEEDS (Spring Show). March 15th and 16th. Mr. G. Forbes, 103, Hyde Park Road, Sec.
BRISTOL (Spring Show). March 12nd and 23rd. Mr. G. Webley, Holm Wood, Westbury-upon-Trym, Hon. Sec.
GLASGOW. March 29th, May 10th, and September 19th and 18th. Mr. F. Gilb. Doughall, 16, Canning Street, Sec.
ROYAL CALLEDONIAN HORTICULTURAL SOCIETY. Shows April 5th, July 5th, and September 18th.
WESTMINSTER AQUARIUM. April 13th and 18th, May 10th and 11th, May 30th and 31st, July 5th and 6th.
TIVERTON. May 24th and 25th. Messrs. A. Payne and J. Mills, Hon. Secs.
MANCHESTER (Grand National). June 2nd to 9th. Mr. Bruce Findlay, Royal Botanic Garden, Sec.
SOUTHAMPTON. June 5th, and August the 5th and 7th. Mr. C. S. Fuldege, 89, York Street, Sec.
MADSTONE (Roses). June 21st. Mr. Hubert Bansted, Rockstow, Maldstone, Sec.
SPALDING. June 21st. Mr. G. Kingston, Sec.
REIGATE (Roses). June 24th. Mr. J. Payne, Treasurer.
RICHMOND. June 29th. Mr. A. Chancellor, Hon. Sec.
SOUTHPORT. July 6th, 7th, and 8th. Mr. E. Martin, Sec.
HELSINGBORG (Roses). July 19th and 18th. Mr. J. Mitchell, Sec.
WIMBLEDON. July 13th and 18th. Mr. P. Appleby, 5, Linden Cottages Hon. Sec.
BRIGBOURNE. July 29th. Messrs. C. Jessop & E. Rawnaley, Hon. Secs.
HEWORTH (Horticultural). August 2nd. Mr. E. H. Feltos, Hon. Sec.
CLAY CROSS. August 15th. Mr. J. Stallard, Clay Cross, near Chesterfield, Sec.
PRESTON. August 16th and 17th. Mr. W. Troughton, Hon. Sec.
SHERWELLY. August 16th and 17th. Admrs. & Naunton, Hon. Secs.
SMATON BURN. August 30th. Mr. E. Richardson and Mr. W. Elliott, Secs.
DUNDEE (International). September 7th, 8th, and 9th. Mr. W. R. McKelvie, 35, Enfield Crescent, Sec.

TRADE CATALOGUES RECEIVED.

Harrison & Sons, Leicester.—Catalogue of Choice Seeds for the Garden and Farm.

Charles Sharpe & Co, Sleaford.—Descriptive Catalogue of Farm Seeds.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BACK VOLUMES AND NUMBERS (B. K. L.).—We have vols. I. and II. bound together, two numbers (13 and 15) missing; vols. III., VII., and VIII., half bound in calf, second-hand. The numbers you specify are out of print.

WILD FLOWERS (H. W.).—It is not likely that a new edition of "Rambles in Search of Wild Flowers" will soon appear.

FUCHSIAS AND CALADIUMS FOR EXHIBITION (A. D. W.).—*Fuchsias*: *Light*, *Arabella* improved, *Starlight*, *Lustre*, *Marginata*, *Complena*, and *Guiding Star*. *Darke*, *Enoch Arden*, *Rhododendron*, *Arakache*, *War Eagle*, *Semeter*, and *Father Ignatius*. *Caladiums*: *Chantini*, *Bellegymy*, *Bicolor splendens*, *Baraquini*, E. G. Henderson, and *Troubetskoi*.

AGE WHEN SEEDS CEASE TO GERMINATE (J. L. Luckley).—There is a long list in Johnson's "Science and Practice of Gardening." We extract the following from it:—"One year: Peas, Beans, Kidney Beans, Carrot, Parsnip, Onions, Herb-patience, Rhubarb, Kim, Poplar, and Willow. Two years: Radish, Salsify, Scorzoneria, Parsnips, the Alliums, Cardoon, Rampton, Alexander, Love Apple, Capsicum, Egg-plant. Three years: Seakale, Artichoke, Lettuce, Marigold, Bona, Rosemary. Four years: Brassicas, Skirret, Spinach, Asparagus, Endive, Mustard, Tarragon, Borage. Five and six years: Burnet, Sorrel, Parsley, Dill, Fennel, Chervil, Hyssop. Ten years: Beet, Celery, Pumpkin, Cucumber, Melon."

POTATOES BITTER (Idem).—Old Potatoes, when they sprout form an alkaloid called solanine, which is bitter and is a virulent poison, the same as is found in the Nightshade, *Solanum dalecarlica*.

SELECT HARDY RHODODENDRONS (Subscriber).—*Ormon*: John Waterer, Barclayham, Blandyham, Caracanth, Mrs. Milner, Sir Thomas Sebright. *Purple*: Mrs. G. H. W. Hensley, Old Post, Kern, nigrescens, Maculatum nigrum, Otello. *White*: Mrs. John Gistson, Duc de Brabant, Minnie, Parity, Pictum, Mont Blanc. *Pink*: Concorum, Stella, Roseum grandiflorum, Lady Frances Ouseley, John Spencer, Byslanum. *Scarlet*: Alarm, Mrs. W. Boydell, Tildan, James Bateman, Lady Claremont, and Francis Dickson.

VEGETABLES FOR EXHIBITION (St. Edmund).—Of Peas *Superbative* has the longest pod, and *Supplanter* is better than *Philbasket*. Dr. Hogg is a fine Pea. They should be sown during the second week in April to be in use by the first week in August, but the season has an influence on the time of Peas coming into use. Cauliflower sown in March on a warm border would be in at the time you name. King of the Cauliflowers is a good sort, and *Walcheren*. Autumn Giant would not be in until later. Sow the Lettuces the first week in May. Snowflake is the finest-looking and best of the Potatoes you name; but for beauty, *Perfection Kidney* (Fenn), and a round sort, *Early Market* (Fenn), are worth notice. What you may grow for a basket of vegetables may be, Broad Beans—*Stevie Long-pod*. French Beans—*Canadian Wonder*. Runners—*Scarlet Champion*. Beet—*Dwarf*, *Dwarf Red*. Celery—*Lochester Red*, *Matchless White* (Williams). Carrot—*James* the Intermediate. Cucumber—*Tender* and *True*. Turnip—*Snowball*. Vegetable Marrow—*Short-jointed Long White*; and we presume you will have Cabbage and autumn-sown Onion, not forgetting a good dish of Tomatoes.

CUTTING-BACK CROTON VARIEGATUM (W. R.).—It will, if cut hard-in, break freely if encouraged to do so by a moist atmosphere and brisk heat, sprinkling overhead frequently, but watering sparingly at the root. The plant for a few weeks (three or four) should be kept rather dry, and when it has broken and made shoots 3 inches long repot, reducing the ball, and water very carefully until the roots are working freely in the fresh soil, and shading for a time until established.

FORBIDDING HOUSES ON WATERY GROUND (Subscriber).—You may, by concreting the bottom of the borders and laying the foundation of the walls in concrete, erect forcing houses, "supposing that the water were to rise through a bed of gravel 14 feet thick to within 8 feet of the surface of the ground," but you must prevent its inundating the fruit borders. We should have the borders entirely above the ground level, which will take you further from the danger of an inundation; and to make sure of the roots not getting into the watery bottom we should lay bricks on the flat on the concrete, and run with Portland cement in a thin mortar state, filling the crevices and covering the surface of the bricks.

CULTURE OF LILIUM AURATUM (E. Wheeler).—The bulbs you have bought-in should be potted in light soil with some sand round the roots. You should plunge the pots in some light material in a cold frame until the growth is an inch or two long, when the plunging material may be removed. If the plants come in contact with the glass they should be removed to a light airy house.

POLLEN (A. R.).—There is no substitute. On the receipt of seven postage stamps with your address the book you mention will be sent post free.

CULTURE OF LAPAGERIA ROSEA (Mrs. C. W.).—This and the white kind would succeed admirably in the cool conservatory, planting out in a well-drained border composed of fibrous peat, watering very abundantly during growth, and at all times keeping the soil wet, though less water will be required when the plant is not growing than when at rest. Do not cut the plants down, but allow all the shoots to remain until they die, then remove them.

TURKISH CUCURBIT (Idem).—Pot the bulbs singly in 5-inch pots in turfy loam with a fourth part of well-decayed manure, and so as to cover the roots to the apex, plunging the pots in a hotbed of about 70° to 75°, removing all offsets before potting, and not watering until growth is somewhat advanced, the roots being in possession of the soil; then water moderately at first, increasing the supply as the plants advance in growth, shifting into 7-inch pots when the 5-inch are filled with roots, removing to a stove or other house where there is a good temperature, keeping well syringed, and apply liquid manure two or three times a week after the plants have the flower stems rising. When blooming they may be removed to a greenhouse.

PROPAGATING VERONICA (E. M. P.).—They are best propagated by cuttings of the young shoots having two joints and the growing points, cutting transversely below the lowest joint, removing the leaves from it, and inserting in light sandy soil up to the second joint about an inch apart, and placing in a hotbed, keeping moist and shaded from bright sun. Plants from seed may be had by sowing in a hotbed and growing-on in heat, hardening-off before planting-out, but they have neither so good flowers nor flower so freely or early as plants from cuttings.

HELBORUS NIGER AFTER FLOWERING IN POTS (Idem).—Harden-off, and plant out on an east border or in partial shade in good rich light soil, and water freely in dry weather.

CUCUMBERS—ROUGH GLASS (J. P.).—In glazing the rough side is usually placed outwards. We have grown excellent Cucumbers in frames similar to those you mention, not raising the plants too early in the season. For summer culture the rough glass affords useful shade, but in the early spring is scarcely admits sufficient light to the young plants; hence we do not advise you to sow the seeds until March, or, which is preferable, to raise the seedlings under clear glass.

CULTURE OF GREEN OLIVE-MELON (H. B. R.).—We have no experience of the kind you send us an engraving of, and can add nothing to that given in the enclosed descriptive notes which accompany the woodcut, which we make out to be that of the ornamental Gourds. Seed to be sown in April in a hotbed, the plants to be potted-off and grown-on in gentle heat, hardening off before planting-out in May or early June on a ridge as for Vegetable Marrows, protecting with a handglass until the plants are established, with the difference only of the shoots being trained to a trellis instead of allowed to run along the ground. A warm situation should be chosen, and sheltered from wind, watering abundantly in dry weather.

OLIVEER FOR NORTH-WEST WALL (F. A. R.).—The fastest-growing climber we know and suitable for the aspect is *Clematis vitalba* (Traveller's Joy). As you do not desire Virginian Creeper, there are no other plants so suitable as Ivy, which in the green and variegated kinds succeed admirably.

CUCUMBER FOR FRANK CULTURE (St. Vincent).—Tender and True is the finest of all Cucumbers, and does remarkably well in a frame over a dung hotbed, attaining to a large size, and is very prolific. If you require a small fruit, then Duke of Edinburgh (Munro's) would suit you, being very prolific, handsome, and good, but only half the length of Tender and True. The other kind named by you is also good.

LITTLE HEATH MELON (Idem).—It succeeds in a frame with a little heat at starting, and by giving air moderately and closing early the fruit ripens perfectly without further artificial heat. We do not consider the Ashpencizer Melon need be grown if you have Little Heath, though in a warm season and situation it, as a ridge kind, affords fine fairly-flavoured fruit.

TAKING OFF SHOOTS—HEADING STOCKS (T. V.).—Take the shoots now or before they begin swelling the buds, and lay them in damp soil in a shady position; and the stocks if large should be cut back at once to within a short distance of where they are to be grafted.

PRUNING CLEMATIS JACKMANII (A. J.).—Cut-back to firm ripe wood, and so as to originate shoots from the base for covering the wall. If you have a large extent of space to cover it may be effected by bringing the shoots down and training them horizontally, or where they may be required.

PROPAGATING EUCYMNUS (Idem).—Take cuttings of the half-ripened shoots in July or early August, and insert in sandy soil either in pots or in a border surcharged with an inch of silver sand, and cover with a frame or handglass. Keep moist and shaded from bright sun; or the half-ripened shoots strike freely in gentle heat in moist soil and shaded.

CAMELLIA FLOWERS DROPPING (T. J. H.).—The flowers drop so soon as expanded from overcropping—a deficiency of root-action, which may be prevented by judicious thinning when the buds are set. Never before have we seen Camellias so floriferous or so fine as they are this season. Top-dress, if

you do not repot, with a compost of equal parts of very fibrous light loam and dried cow dung. The roots come up into that and are much invigorated, as is manifested by the vigour of the plants and healthy foliage. Remove the surface not occupied with roots, and apply the fresh soil about an inch thick if it can be done without reducing too much the water-holding space. We cannot name florists' varieties, they are too much alike.

ROSES—SELECTION AND SOIL (J. L. Thornton).—1st. As to the list of Roses, we should strongly advise you to reject the following:—Aimée Vibert, Anna de Diesbach, Auguste Mlle, Baron Chausand, Empereur de Maroc, Miss Ingram; and though Baron Gonella, Lord Clyde, M. Josephine Guyot, Madame Rivers, and Queen Victoria are good, yet there are better. We should advise you to procure Alfred Colomb, Charles Lefebvre, Marie Baumann, La France, M. la Baronne de Rothschild, Dr. Andry, Marguerite de St. Amand, Abel Grand, Marquise de Castellane, Comtesse d'Oxford, John Hopper, Emille Hausberg, Louis Van Houtte and Annie Wood. We see we have named fourteen sorts here, and only discarded nine, and if you only want twenty-four you will have to omit some others from your list if you adopt those we recommend; and, if so, have only one *Maréchal Niel*, and omit *Beauty of Waltham*, *Jaune Desprez*, *Madame Faloot*, and *Narcisot*, which, though a glorious yellow when it succeeds, is at the best but uncertain. In your situation all the Roses will be perfectly hardy. Dig your beds out deep; beware of shallow beds on the top of a mountain limestone, and obtain some alluvial soil, if you possibly can, from any of the low-lying ground between Ulverston and the Severn, to mix with the turfy soil; but if you use one-third manure you need not use one-third leaf soil as well. You do not want too much carbonaceous soil to start with. The soil on the sides of the roads between Pining and Tockington will make a first-rate addition to your Rose compost if you can procure any. (The writer knows the district well). For your soil and situation have the Roses on Manetti stocks, and not on Briars.

SALT FOR MANGOLD WURTZEL (Buckinghamshire).—Twenty bushels per acre, sown over the surface before the last ploughing.

WEEDS ON PATHS (Clapham).—A saturated solution of common salt applied at a boiling temperature is the most effective destroyer of the weeds. If you apply salt thickly over the walks, that will also kill them, but you must not let it touch the Box or other edging.

WEEDY LAWN (M. D.).—We have no experience of the effects of the substance you name.

CULTURE OF EUPHYRERIA RUBERRIMA (E. G. T.).—These hoots of last year will have been cut-back to the eyes at their base. Early in March the buds will begin to swell, when the plants should be turned out of the pots, and removing all or most of the old soil return them to the same size of pot, employing a compost of sandy fibrous loam and sandy peat in equal parts, and a third of leaf soil, old cow dung, and silver sand, affording good drainage. Place them in a house where there is moderate heat, as that of a vinery or pit, and they will soon start freely, and should have a position near the glass, free ventilation, and be freely syringed. After May they do best in a cold pit, kept rather close, and early closed, so as to have good heat. If you could give the plants after potting the benefit of a hotbed for about three weeks, so as to have the roots active before the tops are excited, all the better. Shift the plants into larger pots as required, watering with weak liquid manure after the flowers show.

SOWING AUCUBA BERRIES (J. H.).—When the berries are ripe sow them in pots or pans in loam with a little peat, covering them about three-quarters of an inch deep, and keep moist, placing in a light airy position in a greenhouse or pit. The outer skin may be removed before sowing, but this is not important. They must not be divided, as from one berry you will only have one seed and plant. The plants will appear in the early part of next spring, the seeds commencing to vegetate in autumn. We do not think you will succeed in obtaining male plants flowering simultaneously with the females, the former in all the varieties preceding the latter.

HOLLYHOCKS (A.).—Black Douglas, black; Andrew Goodfellow, dark crimson; Mrs. Downie Improved, orange; Countess of Craven, rose; and Empress Eugenie, French white.

FORMING VINE BORDER (Amateur).—We should excavate at least another foot, and upon the red sand concrete place 9 inches to a foot of drainage, which will leave you 8 feet in depth for the border, it having proper drains and outlets. The sandstone rock will be available for drainage. We should have liked your border better had you arranged to have part outside, by openings in the front wall admitting the roots to a properly-prepared outside border. It will answer to make the border piece by piece as the vines advance. The kinds you have selected—viz., *Muscat of Alexandria*, *Alicante*, *Gros Colman*, and *Lady Downe's* are excellent for cutting in December, January, and February.

REMAKING VINE BORDER (Subscriber).—It would be better to have the border partly inside and part outside, so much of the former as to admit of the vines being planted inside; but you will certainly have a difficulty with the fine, which must be in the front or near to it—not more than 8 feet from the front wall. The difficulty might easily be overcome by heating with hot-water pipes. Black Hamburgh and *Muscat of Alexandria* are respectively the best black and white Grapes for general purposes. Other good kinds are Buckland Sweetwater, Golden Hamburgh, and Waltham Cross, all white. Black—Black Prince, Madresfield Court, and Vaux's Black Muscat. If you want late-hanging kinds, the best are *Alicante*, *Lady Downe's*, *Gros Guillaume* (Barbarossa), and *Gros Colman*, all black; and *Calabrian Raisin*, *Trebbiano*, and *Syzian*, white.

PEACHES AND NECTARINES FOR HOUSE (Idem).—You wish a few only. The very best are, of Peaches—Crawford's Early, *Dr. Hogg, *Grosse Mignonne*, *Nobleess, *Bellegarde*, *Barrington*, and **Stirling Castle*. *Nectarines*—**Lord Napier*, *Albert Victor*, **Elrue*, and *Violet Hative*. Those marked with an asterisk will suit if you only desire a few trees.

PRUNING PEACH TREES (A Constant Reader).—The bearing shoots should be cut back to 8 or 9 inches, depending, in a measure, on there being at that length of wood a wood bud to which the shoot must be shortened, in no case cutting back to a bloom bud, it being important that every shoot have at its extremity a wood bud. Usually it is safe to cut to a triple bud, having two side plump round buds, and a smaller-pointed one in the centre of those, which is a wood bud. If no wood buds are present except at the base and the extremity of the shoots, such shoots must be left their full length, it being important that the fruit have leaves upon the same shoot beyond it. The short spur-like shoots should not be shortened.

SHRUBS FOR A FIELD (A Subscriber).—At the back of the flowering shrubs we presume you have other evergreens, and taller than the flowering shrubs will be when fully grown, but as you mention shelter we greatly doubt if such

is the case, and to meet this we may hint that we should fill the undotted part as shown in your sketch with *Portulaca Laureol*, common *Kew*, and *Holly*, interspersed with a few *Mountain Ash*, *Laburnum*, double white, pink, and scarlet *Thorns*, double *Cherries*, and ornamental *Pears*, and *Orbs*. Suitable evergreen shrubs are *Arbutus unedo*, *Anoniba japonica*, *Berberis Darwini*, *B. (Mahonia) aquifolia*, *Cotoneaster Simonsii*, *Lagunum ovalifolium*, and *Ulex europaea flore-pleno*, also *Rhododendron ponticum* var., *S. coccineum*, *Deutzia crenata flore-pleno*, *D. scabra*; *Philadelphus coronarius*, *P. coronarius flore-pleno*; *Ribes sanguineum*, *R. sanguineum album*, *R. speciosum*; *Spiraea aristata*, *Douglasii*, and *vailloni*; *Syringa persica* and variety *alba*, *S. vulgaris*, and its variety *alba*; *Viburnum opulus*, *V. dentatum*, and *Wegelia rosea*.

AMATEUR'S PIT (E. H. D.).—The furnace you propose is not too small. It should be the length in grate bar you mention, and the height we should increase by arching the furnace over with firebricks in a semicircle from three courses of bricks above the grate bars, which will give space for smoke after the fire is banked; but the dimensions you give will answer. You ought to have the evaporation troughs, one for the first division, and two in the larger one. They may be formed of cement upon the fire-covers 2 feet long, and the width of the fire minus the thickness of the cement on each side. If 2 inches deep you need not trouble further about depth. The holes in the wall will be of very little use, as you will only have the side heat from the fire. With rubble at the bottom of the bed you might, perhaps, obtain sufficient heat to enable you to grow Cuscutas and Melons satisfactorily. We cannot perceive which of the supplementary remarks are insufficiently explicit.

SLOW-COMBUSTION BOILERS (Bos in Urbe).—We do not know in what their disadvantages consist, certainly none of those you mention. They are not more liable to get out of order, they give equal results, and are not more exhaustive of fuel or labour than other descriptions of boilers, and are well adapted for an amateur; but amateurs having a falling, with other people, to expect too much, we advise a boiler which is above rather than on a level with its work, and you will find it more satisfactory than one which in hard weather must be driven, and the heat, with the increased current, more rapidly escaping by the fire.

MANURING (W. H. S.).—Fowl's dung may be used for Onions, 8 cwt. per square yard, sprinkled on the surface after the seed is sown. Salt and lime make a good compost for Potatoes, five bushels of each to an acre. Gypsum has been applied beneficially to Potatoes, 5 cwt. per acre.

FIREBIRD'S DUNG (Columba).—Keep it dry, and use it as fresh as you can. It is a very powerful manure. Spread it very thinly, and dig it in at once where the crop is to be inserted.

NAMES OF FRUITS (E. Owing).—Bess Peel. We do not recognise the round red one. (*Cornus sanguinea*?)—1, not known; 2, Baxter's Pearmain; 3, Lodgemore Nonspareil; 4, not known.

POULTRY, BEE, AND PIGEON CHRONICLE.

SILKIES.

By REGINALD S. S. WOODGATE.

PART 2.

ALTHOUGH, as we previously stated, we prefer to breed from cockerels and two-year-old hens, still old birds must not be despised in any way, for their continued virility is surprising; we know an eight-year-old bird, some chickens of which found their way into the prize lists last year. This is a fact worthy of notice, for so many of the other breeds are weakened and dull, and are not of any use in the breeding pens after the third or fourth year at most. Silkies, too, when they become two years old are frequently subject to fits of giddiness, and sometimes seem unable to see their food from these chronic attacks; but strange to say, we have never found this go against their productive powers, and a cock we once had so was the father of most of the champions of his year. We have never been able to cure it. For exhibition, Silkies require no especial preparation beyond a good wash. This, however, is essential; for from their fluffiness and silky feathers they accumulate a great deal of dirt, and look when unwashed very bad in the exhibition pen. In washing them care has to be taken, for they are delicate in the water and we have often nearly lost them in their bath. The water rapidly seems to get the better of them, and then they will hang down their heads and die in your hands; but as soon as ever this failing seems coming on we plunge them into a tub of cold water which we have handy on purpose. The action of the cold water, desperate as the remedy may seem, generally seems to recover them. We never use now any preparation such as borax, or blue, or lime, or those quack things to make adult birds white, for clean warm water and white curd soap should do everything. If, however, they fail, the birds are either bad in colour by nature or burnt by the sun and winds, and nothing will then ever bleach them—at least so we find, and we have spent much time in the cultivation of white poultry. They want to be dried by a slow fire, and to be first well rinsed of all soap. A very hot fire will scorch their faces and blister their lobes, which would most likely ruin them for successful exhibition for ever. When they are dry they should be well combed with a coarsely-toothed comb, and their crests brushed back with a hard brush.

In washing them, however, there is one thing which all must guard against. If the water is too hot or they are placed by a hot fire their leg feathers are very liable to come out. This may seem unaccountable, but so it is, and all Silky breeders will testify to it. We suppose that the growth of these feathers is

very delicate, and that they feel the influence of the hot water. We know of several instances where this moulting of the leg-feathering has caused much annoyance, but one illustration will suffice. In November, 1878, we were with Mr. Darby at Stanley Hall, Bridgnorth, helping to prepare the birds for Bingley Hall. Among the other birds to be made ready was a pair of Silkies; they were selected because of their leg feathers, and were washed by the attendant. As they seemed to be suffering from their bath they were removed from the poultry-room fire to one of the indoor rooms, and there as they dried lying by the fire, before the eyes of all spectators one feather after another fell out till they were almost bare on the legs when dry. Thus they were out of the question for the Show, so another pen had to be substituted at the last minute. Not only hot water have we known bring this sudden moulting on, but incarceration in a warm exhibition room or in a basket, or even when the hen is herself incubating. We have noticed it, too, more especially in the hens than the cocks. As a remedy we always tie bandages of linen rags tightly round the legs of the birds to be washed, and do not remove them till the lavatory process is over. We have found, too, rags dipped in cold water and tied round the legs strengthen the leg-feathering. We have used, too, with success a preparation originally given by Mr. Erasmus Wilson for the promoting the growth of and strengthening the roots of the hair; but this is an expensive preparation, which makes it of less use than it would otherwise be.

As the breed now is we think fanciers have to turn their attention to crests, combs, and shape. The five toes seem now understood, and rarely do birds come into the prize lists which have not their claws as well put on as a Dorking; but we see birds winning which are not fluffy enough and which are bad in comb. So lately as the last Crystal Palace Show we saw the first-prize pullet there with a pike to the back of its comb like a Hamburg hen's. This is quite wrong and very ugly; still it escapes notice, for at the Oxford Show, too, a pen was highly commended which had this failing. We consider it a disqualification and would unhesitatingly pass any such combed bird; for the warty-shaped mulberry comb is one of the points of the breed, and any other should be as much a disqualification as vulture hooks in the breed are.

When we look back and see how this pretty little breed has been rescued from becoming a red-combed, lanky, and ugly bird, we are very glad, for only five years ago no one seemed to know what a perfect specimen should be like; and it was not till the perfect and purest birds came from Japan, which bred true to every point, that we were able to lay down the table of required points; and we are glad, too, to notice that yearly they are becoming more recognised and more improved by being less crossed with spurious birds.

In conclusion, we may state that on page 98 in the second part, "wry-tailed" should have read "long-tailed." Of course, we owe thanks from wry-tailed specimens of any breed. We call attention to the printer's error, however, to prevent any mistake, as it is the wry-tailed cocks which breed the coarse and ugly birds that we often see about.

CUTTING THE COMBS OF COOKS.

I ONCE sold to a lady a pen of Game Bantams consisting of a dabbled cockerel and two hens. These birds, obeying Nature's law, increased and multiplied in their season; when I received an amusing and not unnatural complaint, that the birds could not be of a pure race because the little cockerels, unlike the parent bird, had combs and wattles. After hearing an explanation, that to make him quite fashionable the little gentleman sold to her had been shorn of his comb, &c., my fair correspondent condemned the fashion as cruel and senseless, and applied to its former owner no very complimentary epithets for permitting the mutilation; and she was right.

I cannot say with "WILKINS BACON" that I am "glad to see that a case has recently been brought before the Magistrates in regard to the dubbing of the larger breed;" for when we consider that all the shows, Crystal Palace included, encourage and countenance the practice, I think it very hard that proceedings should be instituted against an unfortunate and comparatively obscure individual, and that an officer of one of our leading exhibitions should appear as a witness for the prosecution. Exhibitions which denounce anathemas against trimming, and yet countenance and encourage that which is nothing but trimming, cannot in my opinion be held free from blame in the matter. If it be desirable—which I very much question—to bring the strong arm of the law to bear upon the subject, surely it would be more straightforward, more manly, to select one of our large breeders and exhibitors of Game fowls as the victim. I said above that our shows encourage the practice, and I said it advisedly, for I much doubt whether an undubbed mature bird would win at any of our leading shows, *ceteris paribus*. Taking, therefore, everything into consideration, I must confess that I was pleased with the decision of the Sittingbourne bench.

Yet I should be glad to see the practice abolished. It may be comparatively easily done. At the suggestion of Mr. Fred. Crook (all honour to him for the same) a lady, conspicuous for active benevolence and large-heartedness extended alike to man and all animate creation, offered prizes at the Crystal Palace Show of 1875 for undubbed Game and Game Bantams. Though I feared that most of the birds shown in this class would be dubbed on their return home to fit them to struggle for the honours at other shows, I hailed the event with gladness, as being the insertion of the thin end of the wedge. Let the Palace Committee, then, drive it farther, and make it this year a *sine qua non* that in the classes for Game and Game Bantam cockerels hatched in 1876 the birds must be shown undubbed, or in other words, that birds in these classes if trimmed in any way will be instantly disqualified. In the following year let them drive the wedge quite home, and treat all birds deprived of comb and wattles as trimmed. Other societies will soon follow the lead of the Great National, and dubbing will be a thing of the past.

When Game birds were bred for the arena dubbing was a necessary, perhaps a merciful operation, if the term can be applied to anything connected with the brutalising and degrading sport. Cock-fighting as a national pastime has happily passed away, and with it all necessity for cutting off the combs and wattles of Game cocks. I am only surprised that the senseless practice—senseless because there is no show of reason in its behalf—has so long survived. And is there not every reason against the practice?—a practice which in the more peaceful struggle for the victory in the show pen places the good-combed bird on a level with his bad-combed rival in the hands of a skillful operator. Many and many a winner of coveted laurels would have had to content himself with a third place or high commendation had he not left his comb behind him.

Do away with dubbing, and Game breeders will have another point to breed for, judges another point to consider. Both will be equal to the emergency. We shall then see the aristocrat of the poultry yard at the annual Palace levee arrayed in the coronet with which Nature has adorned him, and the great blot of cruelty will be wiped from the fair escutcheon of the fancy. —SUNNY PARSON.

GAME BANTAMS, AND DUBBING GAME.

"WILTSHIRE RECTOR" quotes the entries at Bristol as a proof that Game Bantams have found their level, which he insinuates is about the equal of Black Bantams. Now, one show is hardly a fair test as to popularity, and such a late one as Bristol more especially. At the Crystal Palace there were thirty-four Black Red Bantam cocks and twenty-seven Black Red Bantam hens against sixteen Black Bantams in pairs. This can be partly accounted for by the liberal classification of the Game, and the reverse will tell at Bristol, where Blacks have the advantage; but still, put them both equal and Game are decidedly the most popular.

Then, if you take a class of Black Bantams, how many are real Blacks with fanned tails and dropped wings? Why, nearly half, and they sometimes win. They are neither more nor less than Black Game Bantams with rose combs and white ears. If someone was to offer a cup for the best Black Game Bantams, it would be a good way for breeders to try for Blacks, and turn the birds with faulty combs, ears, &c., into Black Game.

Now for the dubbing. "WILTSHIRE RECTOR" begins by an unimportant mistake: the Sittingbourne trial is about "Bantams," not "large Game," or so the Kentish journal says. Then he suggests that as they are ladies' pets they might be shown dubbed or not dubbed. Well, so they might, and no really good judge would care whether a bird was dubbed or not if he had a good head. The true test of a head is the depth from crown to end of jawbone, if I may call it so. I have not studied anatomy sufficiently to be sure what the name is, but I mean the continuation of the lower mandible.

The real reason that we want exhibition birds dubbed is this: If a bird is dubbed he can be taken off his run with two or three others, and when he returns can be put down again, and they will soon settle themselves. There will perhaps be a spar or two, but the fags soon recognize their master; whereas, if they get a taste of blood in the first fly (and no pure Game fowl will give in after that, to say nothing of the torture of having their combs mauled, which hurts far worse than dubbing), how long could a bird be kept with his comb perfect? It is bad enough to have to keep them in feather with the rough handling they get sometimes.

There are many mistaken ideas among those who do not keep Game on the subject of dubbing. I have often been asked, "How ever can you stand having your pets dubbed? Does not skinning the throat hurt very much?" I rather astonished a friend of mine by showing him a bird on his run that had been dubbed two days. There was not a sign about the bird that he was not in the most blooming condition, with the exception of three narrow scars where the comb and wattles had been cut

off. No one who knows anything of them would dream of skinning the throat. It is not only perfectly needless, but actually spoils the whole shape of a bird's head. The less you cut off to a certain point the better the bird looks. Of course the comb must be cut level with the head, but there is no need to flay the top of the head.

I have no wish to stand-up for cock-fighting; it unquestionably is one of the worst forms of gambling, and for that reason is certainly deserving of being put down; but I must say that I cannot see as much cruelty in letting two cocks get to each other as in coursing a wretched hare with two dogs, each its superior. The cocks do not want any urging to make them fight, but will do it fully at any time or place; it is "in them," and they do not want teaching. What "WILTSHIRE RECTOR" means by saying that "once let all Game cocks be dubbed, and cock-fighting is for ever done away with" I do not know; but if he thinks that by not dubbing Game fowls he will prevent their fighting, he will find he has made a mistake. This is worse than the "bread-and-milk theory." In conclusion let me say that I quite agree with "WILTSHIRE RECTOR" about the cruelty of our ancestors, but I do not include dubbing as a trace of it. It benefits the bird all his after-life, and the pain is small, as the comb is not nearly so sensitive as other parts of the body.

Let me recommend "WILTSHIRE RECTOR" to devote some of his surplus energies to prevent the "carving" and "stitching" that is performed on Hamburgs and Spanish. They are only tortured to please the eye, while Game are dubbed because it is essential for their welfare. If I was never going to exhibit again I should dub just as much as I do now—that is, all the stags I propose keeping.—FITZ.

BOURNEMOUTH POULTRY SHOW.

The south of England is not rich in poultry shows, and we welcome this new one cordially. The Show was held in the Assembly Rooms, where the light was good and the birds appeared to advantage. The quality was not very superior, and the breeding season evidently kept many of the best birds at home. Mr. John Martin of Fatabull, Wolverhampton, awarded the poultry prizes, and we did not hear one word against any of his awards. Mr. Esquilant judged the Pigeons, and made good work with rather a severe job, as some of the classes were very heavy.

Dorkings had two classes, and came in good numbers. A fine pen of Coloured won the cup; the cock a deep-bodied bird with a grand hen of great size and of beautiful colour. The second cock was also large and very good in comb and colour. In the next class Silver-Greys of great excellence were first. The cock charming in colour and looking very bright, but he had rather white earlobes. Good Whites were second and third with not much between them. Mr. Cresswell's pen was empty. Light *Brahmas* were not a very gay lot. The first old hen was the best bird in the four classes; her colour was good and hackles very dark, and with these points she was very large and well-feathered. Darks were perhaps better, the hens were better than the cocks. A good pullet of very distinct pencilling was first. Third went to a good and cheap hen, which we liked better than the second pullet, for the latter was rather too pale on the breast. In *Cochins* a nice pen of old Buffs were first; the hen of good, clear, and even colour. Second went to a well-grown cockerel of pretty colour, with a fair old hen. In Partridge the first old cock was a large bird, but he did not look quite well when we saw him. In *Game* the cup went to fine Brown Reds; the cock splendid in head and of grand shape and style. We admired, too, very much the first Piles, for they were bold in carriage and neat in head. *Spanish* made about the ordinary show. The first cock was large in face and fair in comb, with a nice hen, and we quite liked the award. In the *French*, *Crêves* of great excellence were first, being very large and deep in body, and of raven blackness. In *Houdans* the hens were better than the cocks, but we have often noticed this at other shows. *Hamburgs* really mustered very creditably. The cup went to good Golden-pencils. The first Gold-spangles, however, must have been close on their heels. The Silver-pencilled were the weakest of all. We liked the markings and head of the third-prize Golden-pencilled pullet, and the first Golden-spangled cock was a grand bird in every way, his comb and colour being first-rate. *Leghorns* only made two pens, and only one prize was awarded. We thought them equally poor, liking, of the four birds in the two pens, Mr. Kitcher's pullet best, but her mate's comb threw them out. Neither had good lobes, and we thought their legs should have been of a deeper yellow. *Bantams* were better in quality than numbers, though some nice Blacks were shown. The Black *Ducks* were in a good light, and many of the pens seemed of equal merit. The winners were of beautiful colour. *Polands* were a grand lot. Splendid Silvers with huge crests first; a marvellous pen of Blacks second, perhaps as good as any pen out for some seasons; and third fine Silvers. There was a pen of *Golden* (Boothby), and a pen of Blacks (Edwards), which we liked,

however, quite as well as the third Silvers. The Variety class was one of the best classes in the Show. White Cochins of great merit were first, but it was a crying disgrace to the Society not to give this breed a class and to let it go into the "refuge." Indian Jungle fowls were second and Black Hamburgs third; pens of almost every other conceivable breed deservedly coming in for high commendations.

The Pigeons were chiefly noticeable for the stud of Mr. Maynard and the Dragons and Fantails; the latter were wonderfully nice. Turbits we thought not up to the usual standard. A lovely Red Jacobin was first in good competition; and in Tumblers a pretty Almond was the winner. Good Arch-angels won first in the Variety class, and Scandaroons second.

We noticed on nearly every pen in the whole Show cards stating the birds were fed and reared on Spratt's food. This is becoming a nuisance, for many of the birds there had never, we heard, tasted one scrap of this food, and yet were ticketed as fed upon it. Of one pen especially we heard the owner say that it had been reared on Dear's food, and never seen Spratt's mixture. We do not say this for one instant disparaging the food, for the value is simply incalculable, but care should be taken in not distributing these tickets on the pens in too haphazard a way.

The Cage Birds made a good show. Among the Canaries the most noticeable was the Ticked Belgian cock of Mrs. Holmes. This bird won the cup, and deserved it, for his shape is simply perfect. The British bird collections were very interesting, but there seemed to be great doubt as to what should comprise the collection, for some cages had twelve varieties, others twelve pairs, and one twenty-four birds, which were not all pairs. Mr. Turner Turner won first with a splendid Raven in grand plumage. Mrs. Drummond exhibited her birds in beautiful condition, but her collection of British birds seemed hardly to obtain its fair deserts.

We must mention, too, that the Hon. Secretary paid anyone their prizes in the room who asked for them, and also the money from the sale of any specimens. This is a good plan, and has already made the Society many friends.

[We have received a list of the prizes awarded, but as it is printed without naming the varieties we do not insert it. A more troublesome form could not be adopted.]

THE CRYSTAL PALACE BIRD SHOW.

The thirteenth annual Bird Show opened on Thursday, the 18th instant. Several of the classes were not so extensively filled as at the 1875 exhibition, but there were others which supplied the deficiency.

The entries of 1875, including duplicate numbers, were 1493, whilst those for 1876 reached the unprecedented number of 1501. The quality of the Norwich birds, Clear, Even-marked, and Ticked, were equal to past exhibits, and the like may be said of the Belgians, London Fancy, Lizards, Cinnamon, Yorkshire, Crested, and the Mules (of the Goldfinch and Canary, and Linnet and Canary crosses), the latter classes keeping up the high reputation of the Palace Show.

The special money prize of £1 was won by Messrs. Mackley of Norwich, as the most successful exhibitors in several of the Norwich classes; whilst the silver cup was won by Mr. J. Doel of Plymouth. First-class silver medals were won by Messrs. G. and J. Mackley (2), and Mr. J. Doel; and second-prize silver medals by Mr. R. J. Pope of Brighton, and Mr. J. Adams (2), which latter exhibitor also won a copy of Mr. R. L. Wallace's "Canary Book," two of which books also fell to the lots of Mr. G. Wones and Mr. L. U. Gill.

The Exhibition was not only larger but of more interest generally to lovers of cage birds, on account of the many rare specimens exhibited, and likewise respecting the seed question. This year prizes were offered for samples of seed, besides other food for insectivorous birds. Prizes were also awarded for nest-boxes—new features certainly respecting birds and bird shows. This I look upon as a step in the right direction.

Concerning the three classes for "not cayenne pepper-fed" birds, they were exceedingly well responded to by many fanciers who prefer birds clothed in a garb different to those pepper fed. In the three classes there were ninety entries, and it would be well if committees or others who have the framing of schedules and the getting-up of bird exhibitions would take the hint and provide classes for non-pepper-fed Norwich birds, for to a certainty, although birds may be made to swallow a given quantity of the heating condiment, many sterling fanciers have objections to it for more than one or two reasons. But the feature in the present Palace Show of classes for non-peppered birds is not altogether new, an extra prize of £1 having for the past two or three shows at the Crystal Palace been awarded to the winners of the most points in the first six classes of Norwich birds not of high colour.

CANARIES.—Norwich.—Clear Yellow.—1, J. Athersuch. 2, G. & J. Mackley. 3, and 5, R. F. Pope. 6, W. Lewis. 7, G. & J. Mackley (3). W. Havers. J. Athersuch (2). J. Benson. J. Doel. opportunity for the exchange of useful information among the members; papers will be read and discussions held on the natural history and proper management of the hive bee; the advice of skilled bee-keepers will be readily given to inquirers, and objects of interest and useful appliances will be shown. The subscription is only 2s. 6d. annually.

CAGE BIRDS AND THE FOOD THEY EAT.

No. 1.

For the past two years in particular food for Canaries and other birds has been a matter of great importance to fanciers, especially canary seed, which has been so extravagantly high in price as to drive many bird-keepers to their wit's end in finding a substitute for it. One fact is beyond doubt—namely, that of bringing into more general use millet seed, which (for a great number of years prior to the recent famine prices of canary seed) was used for Canaries especially in much less proportion than before, and at the commencement of the eighteenth century.

I am pleased to find that special attention is just now being devoted to the food of birds, and no doubt some benefit may accrue from the novel example set forth by the Crystal Palace Company, who at their annual Bird Show, which commences to-day, have offered premiums in the shape of a gold medal as a first-prize, and a money prize for the second, for the best specimens of seed and food appropriate for cage birds.

From an old treatise on Canaries written in French by M. Hervieux, and translated into English, I will give a few extracts of the doings and mode of treatment adopted by fanciers in or about the year 1718. The work in question was printed for Bernard Lintot at the "Cross Keys," between the Temple Gates; and Benjamin Barker and Charles King, in Westminster Hall, in the above-named year. The extracts now quoted will set forth in the writer's own style the various seeds then used, describing the names of such as they were then spelt, the qualities and benefits derived, and the prices realised. M. Hervieux says:—

"I think it will not be improper here to set down the names and qualities of all the seeds curious persons use in feeding of their Canary birds; and for observing of some methods herein I will begin with those seeds which are most necessary for them, and will afterwards proceed to those they may live without.

"The names of seeds proper for Canary birds: rape seed, millet, hemp seed, canary seed, pink seed, lettuce seed, silverweed or tansy seed, plantain seed.

"*Rape seed* is a very small round seed, coming from a plant of the same name. I name it first because it is the most necessary seed for feeding our Canary birds, and they may live with this alone, though they have none of the others, as has been said before. There are several sorts of it; one of them is bigger and blacker than the true rape seed, and commonly kills all the Canary birds it is given to, by reason of its bitterness and other ill qualities. The best is that which is smaller than this bad sort I have last spoken of. It is not quite black, but inclines a little to purple, is very sweet, and has none of the bitterness of the other sorts. It is called French rape seed [at the present day understood by the name of German rape], and that is the best that can be given to birds. It has a nourishing and cooling quality at the same time, so that a bird which lives altogether upon this seed is not apt to grow so fat as those that eat much of the others above-mentioned. When it is too old, as of three or four years, it generally has no more scent than dust, nor scarce any taste, and therefore does not so well nourish the birds that eat of it. On the other hand, when it is too new, though never so good it surfeits them. It must be at least six months old before you give it to your Canary birds; and to prevent being cheated you must lay-in a year's provision before March, so that if it happens to be new it will be at least eight or nine months old, so that it cannot be prejudicial to your birds. To be provided with seed for a year without being obliged to buy again within the time, you need only take nine or ten litrons [a litron is somewhat more than an English pint] for every Canary bird you design to keep, and you will find that enough for the year.

"*Millet*.—A sort of small white grain, round, and at least twice as big as the rape seed. The whitest is the best. There is a yellow sort, which is only good for poultry. The best millet is that of the province of Anjou, on the river Loire, in France. It is sweeter and pleasanter than the rape seed. Its qualities are to nourish, to warm, and to fatten considerably, and therefore curious persons must take heed not to give their Canary birds too much of it; nay, sometimes they must be made to fast. This millet serves for several other uses, which is not to our purpose to take notice of.

"*Hemp seed* is the seed of the plant of the same name. It is twice as big as the millet, and grey. The best is the middling size and bright. Its quality is to nourish, fatten, and heat much more than the millet, and therefore very little of it is to be given to Canary birds, unless in the sharp winter season, at which time it is good for them. The best sort has somewhat

the taste of a small nut, and therefore the Canary birds are very fond of it.

"*The Canary seed* is a yellowish grain, not so thick as the millet, but longer, pointed at both ends. Its quality is to fatten and warm Canary birds. It has almost the same taste as the millet. Many curious persons never give their Canary birds any of it, pretending that it burns their bowels; but it can do them no harm provided they are not continually used to it. I have only a little pinch given them sometimes."

Thus it will be seen from the four above-mentioned seeds M. Hervieux attaches the least importance to the use of Canary seed.—G. J. BARNESBY.

A NEW BEE.

SOUNDS of another new bee come from afar. The Alpine or Ligurian bee has been in this country for many years. Some years after its introduction among us the little Egyptian was received. Some twelve months after it came, the late Mr. Woodbury informed me by private letter that another bee, very much larger than any other species known, was expected either from Australia or Africa, I forget which, but it never came. The new bee this time is an islander of Asia, called the Cyprian bee, and is said to be as much superior to the Ligurian as the Ligurian is to the common bee of our own country.

A gentleman has kindly offered to do his best to multiply stocks and send them to America if £100 be raised to cover expenses; and the question has been asked, Why not have the new bee here as well as in America? The question may well be asked, Why should Englishmen be behind American apirians? It may, for aught I know, be a very superior sort in many senses to our old sort and Ligurians, but we are not yet informed in what sense or way it is superior. A comparison has been drawn of its superiority over Ligurians as they are superior to our old friends. How much is that? Mr. George Fox and myself have watched the Ligurians ever since they were introduced without finding one feature of their superiority, or even the shadow of one. Last year the heaviest hives in Scotland that we heard of were filled by swarms of common bees. In England the best super that we know of was filled by common black bees and exhibited by Mr. Fox at the Crystal Palace Show.

I have been anxious for a public competition between the Ligurian and common bees, and tried to tempt the admirers of Ligurians to enter the arena, but without success. I can see nothing but gain to the public in a trial of this kind. If the old bees beat the Ligurians the bubble of their superiority will burst, and many clever apirians will begin to spend their time in a more satisfactory manner than in Ligurianising; and if the Ligurians run first the stupidity of myself and other stiff-necked men will be rebuked and corrected, if not altogether removed, and that very much to our advantage. I shall be gratified if arrangement be made for a public competition this year, such as Mr. Hales contemplates in his own garden by his own bees.

Doubtless the new bee, the Cyprian, will have a warm reception both here and in America, and owing to a wide-spread love of novelty in both countries there will be "a great run" for it. The love of novelty is implanted in the mind of man, and I most heartily vote for its gratification. To the gentleman, whoever he may be, on whom fell Mr. Woodbury's mantle, I would like to say, Please let us have the Cyprian.—A. PARRICRAW.

HARVESTING HONEY.—No. 4.

SECTIONAL SUPERS.—In the current number of the American "Bee Journal" Mr. C. B. Isham has published instructions how to make his pretty little supers which I figured in my article of December 9th last. Slightly abridged, these instructions are to the following effect:—

The tops and bottoms may be of any kind of wood—soft preferred, but hard wood admits of polishing and making as ornamental as may be wished, especially useful when the variety is wanted for exhibition. Dress to proper thickness—say three-sixteenths of an inch—varying with size of box required, and cut entrance slots in bottom pieces; the metal corner is a seven-sixteenth-of-an-inch strap of tin bent at right angles and pronged at each end, making the length from shoulder to shoulder the same as length of glass for height of box; with prongs long enough to pass through wood; bend over, and make a square clinch as shown in top of super in out. In each corner of wood, at proper distance from edge, make a narrow mortice for prong of tin corner to pass through, and inside from mortice, average thickness of glass distance, make an awl-hole in which to drive a three-eighths-of-an-inch brad to hold the glass from falling inwards.

Having cut the glass to the proper size the super is ready to put together. Through each mortice in the bottom wood pass the prong of tin corner, bending projection down flat on the outside surface, then stand on the bench or table with sides fronting you, and it is in position to receive the glass. First put in the sides, resting them in the respective corners of tins; then with

the right hand put the end glass in its place; now slip in the other end glass, for the present not giving it much attention. You are now ready for putting on the top (to which has been fastened guide comb), by taking it in your right hand and slipping one end on prongs just far enough to hold them together; then reversing the position of the hand change operations to the other end of the box, drawing the corners to place, inserting prongs on mortice the same as at the other end of the box, and press top squarely down till the points of the brads are even with the tops of the glass; then take the box in hand, and with a narrow stick inserted in slot crowd out the end glasses flush to place; press top on lightly and hammer down light to glass; clinch, and the box is completed. Three sizes are principally made as follows:—

For narrow single-comb box: wood, 6½ by 2½; glass, 5 by 6 and 5 by 2. For two combs: wood, 6½ by 4½; glass, 5 by 6 and 5 by 4. For three combs: wood, 6 by 6; glass, 5 by 5½ and 5 by 5½.

These small supers are used on any kind of moveable-comb hive by removing the crown-board and laying strips quarter of an inch thick across the frames for the boxes to rest upon; put on all the boxes the hive will hold, covering with a tight outside cap. In making quantities of these supers it is advisable to have a thin board pattern with mortice and nail holes in proper places, so fastened as to admit of slipping under it the wood to be morticed and bored. By driving your chisel through the pattern holes your wood will all be prepared alike, and provided your glasses are also cut accurately to gauge the supers can be very rapidly made. Figs. 39, 40, which represent "The American" moveable comb hive, will give a good example of how

Fig. 39.

sectional supers are filled. It will be noticed that the frames (which are removable from the side) do not reach the top of the hive by 2 inches, and in the space thus obtained are placed one tier of supers directly on the frames. When these supers are nearly filled they are gently lifted up, bees and all, and boxes with openings through both tops and bottoms are placed beneath, through which the bees pass to and from the boxes in which they are working. The difficulty of inducing bees to commence in new boxes after the first set is filled is thus overcome, and it is only necessary to remove the upper tier when finished, and elevate the lower boxes as before, to keep the bees constantly at work while the honey harvest lasts.—JOHN HUNTER, *Eaton Rice, Haling.*

Fig. 40.

OUR LETTER BOX.

MARKING YOUNG CHICKENS (H. H.).—The younger they are when marked the better. Punch a hole with a strap-leather punch through the web of the wing. One hood may have one wing marked, the other brood both wings.

TUMBLER HEN'S SMALL EGGS (Old Bob Bidley).—We are afraid your hen Pigeon has done her work at seven years old; she might deserve the prefix of your own name. The first and last eggs of a bird are always the smallest. In a young one it is a sign the secretions are at fault, in an old one the functions are worn out. We can only advise you to attend to her diet. Give her bay salt, old Egyptian beans, and some pellets made of barley meal, with one quarter of powdered camphor, the whole mixed with milk, each the size of a small pea.

PATAGONIAN RABBIT BURROWING (C. E. A.).—We do not believe that Patagonian Rabbits would burrow their way out from any confinement. It is against their nature. Neither they nor the Silver-Gray burrow. It would be easy for the Silver-Gray or the Hare Rabbit to adopt the habit from their activity, and these bred between them and the wild Rabbits do so. The Patagonian is, however, from shape and bulk unfitted for the process. The foreign Rabbits have more of the habit of the Hare, and squat or sit in forms all day.

HIVE WITH COMBS (J. O.).—The combs made by your swarm last year will be of great service to a swarm this year. As soon as a swarm shall be cast amongst the combs eggs will be rapidly set and honey rapidly gathered. Amongst such combs bees do an extraordinary amount of work for some days. When the combs become filled with brood many nurses are needed, and less honey is gathered.

REMOVING STOCKS (O. H. W.).—You should remove your hives now, at a time when all the bees are at home. Let both hives be placed in the new position as they stand to each other now. Confining the bees to their hives afterwards will do no good; but you may lay a small branch of a shrub on each flight board to attract the attention of the bees when they come out, and make them see and understand that an alteration has taken place. Not a bee will be lost by the change of position.

DYSENTERY IN BEES (A. B.).—We have never tried the remedy for dysentery which your friend recommends—viz., "A quart of syrup, with a gill of brandy and a spoonful of salt in it." If brandy affects bees as it does men, the remedy named would make your bees very jolly. For dysentery we use loaf sugar and pure water only, and have never found anything else so efficacious. Bees without queens at this season are not very demonstrative; they do not search for them, or make manifest their loss by noisy panting, as they do on the death or loss of their queens. As queens are now laying, you will be able to ascertain by an internal examination whether your hive has brood in it or not. Some two years ago we gave a list of nearly one hundred plants which yield honey. All that you can raise from seed or by planting in your garden will not help your bees much. They will find plenty of honey in the flowers of the orchards, fields, and forests in your neighbourhood.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

16th.—Rain commenced at 9.45, and continued till noon; very dull all day.
17th.—Rainy morning, and shower at times all day.
18th.—Fine morning; thunder about noon; showery afternoon; and very wet evening.
19th.—A very fine day throughout.
20th.—Fine morning; heavy rain soon after noon, continuing for two or three hours; showery afternoon and evening.
21st.—Rainy morning; showery day; very windy in the latter part, and at night.
22nd.—Windy in the night and early morning, but very fine all the early part of the day; rather showery towards evening, but very fine night.
Very much warmer than last week, nearly 15°; and also more showery and windy.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 22.

Prices of all kinds of best fruit have an upward tendency, the supply getting shorter. The market is well stocked with early-forced vegetables, the Channel Islands sending good samples of Ashleaf Kidney Potatoes.

From observations taken near London during forty-three years, the average day temperature of the week is 49.1°; and its night temperature 32.5°.

NEW ROSES.

O buy a pig in a poke is a trifle compared to the buying of the new French Roses. I have over and over again bought every new French Rose that has been sent out, and certainly not one in twenty has been worth growing. The descriptions of the raisers are as much to be depended upon as the gushing language of the circulars of advertising wine merchants. The nutty, old in bottle, soft velvety of Messrs. Swipey & Co. are adjectives as delusive to us poor parsons as the superb, vigorous growers, pure transparent rose colours, quite a novel colour, beautiful satin Peony Rose of the French Rose tints, are to rosarians. "Tis all," as a dissenting country cobbler called elastic-side boots with buttons on them, "tis all a deception."

Now, take the year before last. There were only two Roses out of the whole lot which were worth growing—Madame Marie Finger and Capitaine Christy. Last year I do not know that a single good Rose was sent out from France. With regard to Capitaine Christy, men bought that because it had received a first-class certificate at the Lyons Show; and this year there is a Rose sent out called Triomphe de France which has been (I presume at Lyons) exhibited as a seedling, and received its name from the Judges who awarded it a gold medal.

Here we have a Rose that we can safely buy; but looking through the list I can find no other with this diploma, and the only protection we have for the others are the names of the raisers. We can generally depend upon M. Lacharme, although I never can see the beauty of his wife (Madame Lacharme) which "D. Deal," raves about so (of course I refer to the Rose, and not the lady of the name). But taking the useful calendar of my friend Mr. Reynolds Hole as a guide, I find that very few of the raisers have of late years sent us an acquisition.

But when we turn to the English nurserymen the case is quite different; they, as a rule, never send out a Rose till they have proved it. Take Mr. George Paul for instance; he has given us S. Reynolds Hole, Wilson Saunders, Duke of Edinburgh, and Princess Mary of Cambridge. Mr. Turner, too, has sent out capital Roses, notably my namesake. And, by the way, I am happy to tell him that I find from my tailor that I am gradually assimilating my form to my namesake, and am really becoming globular. Oh, how I have been chaffed about the description! I have had every kind of paper sent me from the "Pall Mall" to the "Family Herald," with the same old chaff in it about my globular form. Well, I am a very good Rose at all events, and there is no form so beautiful as the globular.

Then Mr. Turner has three more good Roses this year—Oxonian, Miss Hassard, and Royal Standard. Mr. Cranston, too, has sent out a gem of the first water, one worthy of the great name—Sir Garnet Wolseley; and there are several more English novelties, which from the reputation of the raisers, no doubt, are worth buying, so

No. 772.—Vol. XXX., NEW SERIES.

that we really need not waste our money on French novelties. The purchase of these latter is a most severe annual tax to our leading nurserymen, and I am sure they would all be delighted if there was no demand for improved French novelties.—JOHN B. M. CAMM.

NEW AMARYLLISES, WITH CULTURAL NOTES.

THIS genus of stove and greenhouse plants has a very wide geographical distribution. Many of the species are merely valuable as botanical specimens, others of them are really splendid flowers, and when well grown form a gorgeous display in the plant stove or conservatory. The countries from which most of the popular species have been introduced are Brazil, which gives us *A. reticulata*, *psittacina*, *fulgida*, *aulica*, and others. From the Cape of Good Hope we have *A. pumilo*, *revoluta vittata*, and *vittata major*. There are also representatives of the genus to be found in the East and West Indies, North and South America, the Crimea, Japan, and quite recently a deep yellow-flowered species from Cuba. From Peru the Messrs. Veitch were fortunate in obtaining, through their late collector Mr. Pearce, the splendid *A. Leopoldi* and the no less distinct species *A. pardinum*. These two last-named species have been used to hybridise some of the finest species and varieties already in cultivation, and the one from which I believe the best results have been obtained is that brilliant-coloured dark-crimson variety *A. Ackermannii pulcherrima*. *A. Chelsonii* was exhibited on a previous occasion; it is as brilliant in colour as *Ackermannii pulcherrima*, but a great advance on it in the formation of the flowers; the segments are more rounded, and the flowers more broadly opened and symmetrical; the colour is orange crimson. Brilliant is another striking flower, with the scarlet shade predominating. *Maculata* was exhibited the same season (1872). To all the above first-class certificates were awarded. Again, the Messrs. Veitch exhibited a collection of no less than forty-two distinct varieties at the Royal Horticultural Society's meeting, February 16th, every one of them worth growing for decorative purposes, and the colours of the flowers were quite as remarkable as their high-class quality. Indeed it may be truly said that this group of Amaryllises contained some of the most strikingly novel flowers ever seen in England, or perhaps any other country. Five varieties were selected by the Committee for first-class certificates, and a large proportion of the others that had names attached were not inferior to those so honoured. The following notes I made of the flowers as they were exhibited, and the first five named were certificated.

A. Junius.—Flowers of excellent shape, 6 inches across, rich crimson scarlet, with deep crimson shade at the centre of the segments.

Sultan is a very distinct flower of handsome shape; the segments slightly recurve and give a very elegant appearance to it. Colour crimson, with distinct shade of claret.

Agatha.—Well-shaped flowers; the centre reddish

No. 1481.—Vol. LV., OLD SERIES.

crimson, the outer edge of the segments edged with creamy white.

Rev. J. Stainforth is the largest and best-shaped flower in the collection. It measures nearly 7 inches across. The segments are marbled and spotted with crimson; the centre is pale yellowish white, with lighter stripes down the centre of each petal.

Phæbe.—Dazzling scarlet, with a greenish yellow centre. A very striking flower.

Thomas Moore is well worthy of the name it bears. The flowers are of the largest size, in the way of *Junius*, but sufficiently distinct from it.

Medea.—Purplish crimson, with greenish centre.

Electra is of the pardinum type, and the best I have yet seen of this class; the crimson spotting on a pale yellow ground is very effective.

Kara.—A large reddish crimson flower, the segments beautifully rounded at the edge. The shape is very perfect.

Camilla.—This is a very pretty flower and the lightest-coloured one in the collection. The segments are creamy white, marked at the base with crimson.

To the above I would like to add a few remarks on culture. In the first place a suitable compost must be obtained. I have tried various composts, and have been most successful when good turfy medium loam was used, adding only some well-decayed stable manure and a little sand. A mistake is made if the pots are large; 6-inch pots are sufficient for the largest bulbs. The small bulbs are potted in 60's and small 48's. The best time to pot is when the bulbs are at rest. After carefully draining the pots place some very tough fibrous loam over the drainage, then fill the pot with the compost. The bulb should not be planted deeply; quite two-thirds of it should be above the surface, and the mould should be pressed in quite firmly. Our bulbs were potted this season a week or two before starting them. The bulbs had been in the pots in which they had flowered, and the pots were placed after growth was completed in a coolinery, so that they had at least three months of a resting period.

I prefer to start the bulbs in a temperature of 55°, increasing it if the flowers are required early to 65° at night after the flowers show. This year they were placed at once on a shelf in the Pine house, and they have done remarkably well. The succulent roots protruding as thick as goose quills and in great abundance above the surface mould in the pots, and the corresponding sturdy growth of the plants, show that they have the treatment they require. Some growers recommend that the pots be plunged in bottom heat at the time they are started into growth. I have tried this, and do not think that it is so satisfactory as placing the pots on shelves near the glass. We water sparingly at first, but when the fresh roots have reached the sides of the pots water is applied more freely. The atmosphere of the house is kept only moderately moist. The flowers sometimes show before the leaves, sometimes flowers and leaves come up at the same time, and not unfrequently the leaves make considerable progress before the flowers throw up. Like most bulbous plants the *Amaryllis* comes to its full development very rapidly. Two to four flowers are the usual number on the stalk, and when the first that opens is about fully developed the plant may be removed to the show house, where the flowers will continue in beauty for a week or ten days. Of course if they have been in a night temperature of 65° it will not be good management to expose them all at once to the free air of a greenhouse or conservatory; draughts of air would certainly injure the flowers. One end of the house should be kept closer for a few days after plants have been brought in from the forcing houses.

When the flowers have done blooming the plants are again placed in heat until the bulbs have completed their growth, and until that period they are watered freely; but when the leaves show signs that the bulbs are nearly ripe water is gradually withheld, the leaves fade, and no more water is given until it is time to start them into growth again. All through the growing period the plants are fully exposed to the sun.

I have made the above remarks on culture, having found the system to answer. But the *Amaryllis* is becoming almost universally cultivated, and other raisers of novelties besides the Messrs. Veitch are at work. Mr. Williams of Holloway has exhibited some fine flowers of a different type. A large number of very fine seedling forms have been exhibited from the gardens of Charles Kieser, Esq., of Broxbourne, and Messrs. E. G. Henderson & Sons have a large collection. No

doubt there are other cultivators who have had different experience, and any cultural notes would be very useful from them.—J. DOUGLAS.

ROSES ON THEIR OWN ROOTS.

I WAS rather surprised to see in one of the late numbers of the *Journal of Horticulture* that Mr. Camm altogether condemns Roses on their own roots. There are a few kinds that strike readily from cuttings taken with a heel even as late as October, and make good plants in a short time.

In October, 1875, I put in about a thousand cuttings of about twenty of the best varieties. They were taken with a heel and were well trodden in a trench made as if for planting Box, a little sharp road sand being first put at the bottom of the trench. The result was that Countess of Oxford, John Hopper, and Edward Morren almost all grew, and by the autumn made plants having beautiful roots as large as the plants on *Manetti* usually supplied by the trade. They were taken up in the autumn of 1874 and planted out in beds, and by last October had made capital plants, many of them having produced blooms fine enough for competition at any but the best shows. I put in more cuttings in October, 1874, with very much the same result as to the varieties which struck best. Some kinds—*Madame Vidot*, for instance—would not strike at all, but those which did strike grew for the most part as well as could be desired.

When John Hopper first came out I struck about a dozen cuttings of it taken from forced plants; they made fine plants in the course of two or three years, and are still in a prosperous condition, producing annually a fine crop of blooms. In short, I am much inclined to think that Roses on their own roots are not the mistake which Mr. Camm believes them to be. I have grown Roses by thousands for a good many years on the common Briar, the seedling Briar, and the *Manetti*; but I think that if I were about to establish a rosarium now I should go in for H.P.'s on their own roots. Teas do much better as a rule on the common Briar.—B. B. P.

LIBONIA FLOBIBUNDA CULTURE.

As a greenhouse plant there are few more worthy of cultivation than the above. Insert the cuttings in March, twelve in a 48-pot. They will strike freely in a compost of turfy loam and silver sand, the pots to be placed in a gentle hotbed. When rooted pot singly into 8-inch pots, using three parts turfy loam, one part old cow manure, one part silver sand, with some small pieces of charcoal. When established harden-off and grow in a cold frame, shift into 48-pots before the roots are matted together, and never let the soil become dry. In September move the plants into the greenhouse, affording them a light position and a temperature of 40° to 45°. The plants will flower freely from January until April, and will not disgrace the dining table or the drawing-room, the small bright green foliage with the orange and dark brown flowers being very effective. After flowering move them into a temperature from 55° to 60° to make new growth, harden-off, then move them outdoors.

Libonias make nice standard plants. Cut off all side shoots until 18 inches high, then stop as required to make a nice head 18 inches over, which they will do the first season with but little care. Place a plant in the centre of a fruit-stand with fruit round it. Place the stand in the centre of the dining table, and with a good plant of *Gesnera Bewleyi* on each side the effect is most beautiful, especially by gaslight. The *Libonia* will not flower in a high and moist atmosphere.—G. S., *Faulkners House Gardens*.

EXHIBITION OF CLEMATISES.—We are informed that Messrs. Jackman & Sons of Woking have made arrangements to hold an Exhibition of Clematisses in the Royal Botanic Society's Garden, Regent's Park, similar to the gorgeous display which was made last year. The exhibition is to be opened on the 1st of May.

THE ARRANGEMENTS OF COLOURS

IN THE BEDS OF THE LONDON PARKS AND GARDENS.—No. 8.

THE designs submitted are distinct from those which have been previously figured. The effect of the beds when planted was very good, and the arrangement of the colours was gene-

rally admired. The designs are simple in outline, and the plants employed are of quick propagation and easy culture.

BED M.

1. *Champeucea diacantha*.—White spiny-foliage plant of a very striking appearance, forming a fine contrast when grouped

with other plants, and for ornamental bedding it is unequalled by any plant in cultivation with similar foliage. Sow seeds in March in a gentle bottom heat, transplant the seedlings in pans as soon as they are large enough to handle, pot them as they get larger, keep them growing, and they will be fine plants to go out by the end of May.

Fig. 41.—Bed M.

2. *Lobelia Blue King*, light blue.
3. *Alternanthera paronychioides major*.
4. *Alternanthera amoena spectabilis* (new), magenta red.
5. *Golden Pyrethrum*.
6. *Echeveria secunda glauca major*.—A distinct and very fine hybrid between *Echeveria secunda glauca* and *E. metallica*.

The leaves and the whole character of the plant resemble *E. secunda glauca*, but are larger than that species. The plants are stemless, and form semi-globular tufts. The plant is of free growth and strong constitution. It is a fine addition to the summer-bedding succulents. It is propagated by offsets, which are produced freely.

Fig. 42.—Bed N.

BED N.

1. *Fuchsia Golden Fleecce*.—The style of growth is dwarf and branching; leaf medium-sized, very glossy, and shining like gold; the flower-buds (including tube and sepals) are light crimson; the corolla blue. The plant grows freely, and the more it is exposed to light, air, and sunshine, the brighter is

the colour of the leaves. Cuttings struck in the spring make the best plants for beds.

2. *Achyrocline Saundersonii*, silver foliage.
3. *Lobelia Blue King*, sky blue colour.
4. *Golden Pyrethrum*.
5. *Echeveria secunda glauca*.

6. *Alternanthera magnifica*.
7. *Lobelia White Perfection*. One of the best of its class.
8. *Stellaria graminea aurea*.
9. *Cerastium tomentosum*.—N. COLA, Kensington.

USEFUL FRUITS.

DISCUSSION on useful hardy fruits is always valuable, but doubly so, it must be admitted, when conducted at a seasonable period of the year—that is, the period at which the trees may be planted. Yet information on the subject can never come amiss, for it costs nothing in storing, but, on the contrary, may acquire a greater value by keeping. Information, therefore, whether applicable to the ensuing spring or subsequent autumn, cannot fail to meet with general acceptance. At the present moment remarks on this subject are applicable to either season, for fruit trees may be safely and successfully planted now, or the work may be deferred until the autumn.

Autumn planting is advocated on the ground that the trees will emit fresh roots before winter. It is true they will do so if planted early, say in October or early in November; but if planted after the middle of November not one tree in a hundred will emit fresh roots until the following March. I have frequently taken up and replanted trees when the buds had commenced swelling, and they have flourished quite as well as others which had been planted one to two months earlier.

In late planting too much importance cannot be attached to keeping the roots moist (they must not be dry for a moment), and then the trees will re-establish themselves quickly. Drying of the roots of fruit trees should at all times be avoided; but in early-autumn and late-spring planting special care must be taken on this point, even if the syringe must be brought into requisition to counteract the drying effect of the atmosphere.

I will now refer to the two main questions propounded on page 129—namely, What form of tree is the most useful? and what kinds of Apples, Pears, and Plums are the most profitable? In approaching this question I not only seek to convey, but hope to elicit, information. I am willing to contribute my mite of experience, but I do so under a profound conviction that I have much to learn.

When I commenced fruit-growing (on the ordinary scale usually practised in gentlemen's gardens) about twenty years ago, I confess to having felt tolerably competent, and I fear I did not entertain the same respect for the opinions of others as I do now. I thought then that I had not much to learn, but I have found since that I have had a great deal to unlearn. Young men, do not hesitate to unlearn if the teachings imparted by others (or your own inherent notions) are unsound. A measure cannot be filled until it has been first emptied. Those of sanguine temperament, holding extreme views, have frequently much to unlearn at some time or other during their lifetime, and I have had twice to unlearn on the matter of fruit trees.

I was once firm in the conviction that to produce useful fruit in a profitable manner, that Apples and Pears on free stocks and not pruning the trees was the correct mode to adopt, but the plan exhausted my patience; and without attempting to adjudge it wrong, I cannot admit that if exclusively adopted it is right. It is a plan that should be adopted, but only in conjunction with other modes and with such modifications as to pruning which experience has proved to be advisable.

From that extreme I went to the other, and followed up the "dwarfing" system with all the ardency of a young convert. I would hear of nothing but "Paradise" stocks, "finger and thumb pinching," and "root-pruning." I thus raised trees—little prodigies—which the natives came to wonder at, admire, and feed my vanity. There they were and there they are—some of them, that have not "gone dead"—pomological dolls, stunted, overworked, crippled, little slaves living (or dying) "fast" lives of forced labour, and not "leaving a good name behind them."

Labour by the lash cannot be profitable without being cruel, whether applied to trees, beasts, or men; and as I hate cruelty I have sought for profitable returns of fruit by the rational system of guiding and tending, rather than by the greedy, harsh, practice of whipping and cutting. I have arrived at the conclusion that it is as reasonable to whip and drive a child into manhood—that is, to hasten the growth of bone, and sinew, and intellect by flogging—as it is to attack the sources of life of a young tree; to pinch it above and cut it below equi-

timally, and expect it, to the greatest extent of its nature, becoming profitable. Thus I do not on the one hand believe that a tree should be permitted to grow unpruned and untended, or, on the other, that it should be mutilated by a practice which is falsely termed art. I believe in doing justice to the tree, also to the intelligence of man. His prerogative is to "dress and to keep," but not to destroy.

But in considering the question of the best form and character of the tree by way of producing in the fullest manner "useful fruit," we cannot in practice dissociate from the subject the element of "time." Were the matter to be decided regardless of time, then indeed little discussion would be needed; for it is, and in all probability will be, the well-tended orchard trees which will meet a nation's demand for fruit, or at least those in connection with espaliers, for the latter have in the past proved valuable adjuncts to the former, and espaliers in the future are unquestionably capable of yielding a maximum supply of fruit under a minimum outlay of ground, space, and labour.

There is no lack of would-be authorities on fruit culture who dogmatize on the subject as if time were of no moment; but in point of fact and in actual practice it is of the very first importance. So important has the element of time been in the past, that it is to its influence more than anything else that useful hardy fruit trees have not been more generally planted.

It is not often that we find the question disputed that fruit trees are profitable, even fully as much or more as than ordinary garden and field crops. Most people admit that freely, yet they hesitate to plant on account of the years of waiting which they feel must be endured before their harvest can be reached. It is all very well to remind such of the benefits derived from the works of their ancestors, and to urge as a corollary the duty of the present generation to provide for the wants of posterity. That is all very reasonable; but as a matter of fact those who invest like to do so in a manner of which they can have a reasonable probability of seeing and enjoying the fruits of their enterprise. They have as great right to do this in fruit culture as in any other mode of investment. It is easy to denounce with dogmatic assurance the system of growing fruit by an artificial mode of culture, and employing precocious stocks, but it is only by such stocks and such culture that many, who desire to have fruit in their gardens, can hope to live to see it there produced.

If I had a garden containing no fruit trees I should (although I am not in the "sere and yellow leaf") most assuredly plant Apples on Paradise and Pears on Quince stocks, not because of the innate superiority of those stocks as being, half a century hence, the most profitable, but simply on the question of time. Time, I urge, is of paramount moment and must be considered in the question of fruit culture. We can no more ignore the advantages of railways or successfully endeavour to prove the superiority of animal locomotion than we can set aside stocks of a quick fruit-producing nature, or successfully adjudge them inferior to the slower-bearing trees. Comparisons indeed between the two modes of locomotion and two plans of fruit-production cannot be reasonably instituted by way of proving the superiority of either. They are not antagonistic, but each is allied to the other naturally and profitably. We must adopt both modes; and if we make the best of them our reward will be greater than by pinning our faith and concentrating our energies on one system alone.

Both plans of fruit-production are good—dwarf and standard—if they are used and not abused. The dwarfing system has been abused by whipping infantile trees into bearing with as much reason as yoking a two-year-old colt to the plough and flogging him on in the killing work. Orchard trees also have been abused—the abuse of starvation—by sticking them in "under the sod," and leaving them to struggle on with little support and attentive care. Neither of those plans are the most useful or profitable; but if the trees of both descriptions are rationally treated they will yield such returns as will prove their value, and will silence in the most complete manner those who in the full pride of a pet dogma produce little beyond the usual crop of wild notions. I will, with permission, refer to this subject on a future occasion.—AMATEUR ORCHARDIST.

ROSES FROM CUTTINGS.

NOTWITHSTANDING Mr. Camm's undoubted renown as a rosarian, let me recommend "St. Edmund" to try growing Roses from cuttings. I assume he means to force them; and if so, Teas, with which I am best acquainted, will serve him well.

By this I mean that he will find cuttings of these root well, grow well, and bloom well in what I consider a moderate length of time from taking them from the parent plant.

I have some plants which are not any of them more than a year old, some not more than ten months, and they are from 15 to 24 inches high, with one, two, or three principal shoots, and from one of them I, this morning, cut a lovely bloom of Catherine Mermet. They will bloom more freely next year I admit, but they are pretty, healthy, and symmetrical plants now.

I think it right to add that I began cutting blooms on December 26th, 1874, and hardly missed a day until the outdoor plants came into flower. This year, in consequence of the wet season, the wood did not ripen, and they are nearly a month later.

"ST. EDMUND" may likewise be encouraged by the knowledge that I do not keep a qualified gardener, that I live in the middle of a manufacturing town with a factory chimney at the south-east corner of my garden, and that the only space I have for forcing is that under some Vines in an 8-foot section of a lean-to house 14 feet wide.

On an old plant of Souvenir d'un Ami on its own roots I counted twenty-five flowers in different stages of growth, all showing colour about a fortnight ago. So much for the dictum that these plants do not bloom freely.—E. L. W., Yeovil.

ROYAL HORTICULTURAL SOCIETY.

MARCH 1ST.

FRUIT COMMITTEE.—Henry Webb, Esq., in the chair. A brace of Cucumbers was received from Mr. Owen Thomas, gardener to Sir Robert Peel, Drayton Manor. The variety is the result of a cross between Telegraph and Masters' Prolific. It partakes more of the character of the latter than of the former, but was not considered sufficiently distinct. Mr. Thomas was awarded a letter of thanks. Mr. Thomas McLure, The Gardens, Hartley Grange, Winchfield, sent roots of Black Alasce, a long black Turnip, which is very hardy and very valuable for winter use. It was decided to have it cooked, and a report to be made upon it at the next meeting. Lady Holland sent a dish of Birmingham Stone Pippin Apples grown at Holland House, Kensington, which were in very fine condition, and a letter of thanks was awarded. A dish of very finely flavoured Old Colmar Pears came from the garden at Chiswick.

FLORAL COMMITTEE.—W. B. Kellock, Esq., in the chair. It would not have been surprising, considering the miserable state of the weather—the persistent downpour of rain—if both horticulturists and plants had been absent from the Council-room on this the first meeting after the ratification of the "Treaty of Peace." But peace, usually bringing prosperity, fostered a willingness in several floral caterers to make an attractive exhibition, the mildness of the day further favouring the safe removal of tender plants.

A most beautiful group of Orchids, interspersed with a few choice Palms, was exhibited by Messrs. Veitch & Sons. The Orchids comprised about fifty plants of Dendrobies, Odontoglossums, Cypripediums, Phalenopsis, &c. Odontoglossum Pescatorei had a splendid spike with eight branchlets and a hundred flowers. Odontoglossum gloriosum had a remarkably dense spike of over fifty flowers. Near it was an unnamed "species," or variety, of great beauty, apparently intermediate between O. gloriosum and O. Alexandræ. O. triumphans had a very fine spike 4 feet in length. Angreum citratum had a lovely spike of fifty pearly white flowers. Odontoglossum Boecklii was in lovely form, and the Dendrobium crassinode, Wardianum, &c., were in good force and fine condition. Noticeable also was a small plant of Dendrobium Ainsworthii, a cross between D. heterocarpum and D. nobile, very distinct and chaste. Masdevallia nyctetina was also exhibited; it is a singular species, the flower being buff with purple maroon spots and horns; it was springing from the root and resting on a mound of moss. Ada aurantiaca and Dendrobium Jamesianum were also very attractive. The collection was highly commended by the Committee.

Mr. B. S. Williams also exhibited a very gay miscellaneous group of fine-foliated and flowering plants, consisting of Palms, Ferns, Orchids, Eucharises, Bertolonias, Amaryllises, Anthericum variegatum, &c. In this group Calanthe Turneri, Cypripedium Dayanum, and Zygopetalum crinitum were specially noticeable. Habrothamnus elegans argenteus was exhibited, the foliage being nearly white. The Bertolonias Van Houttei, superbissima, &c., were also attractive. Mr. Williams also exhibited a dozen plants of Primula sinensis fimbriata of a remarkably robust strain. Also as new plants, Odontoglossum membranaceum superbum; Masdevallia polysticta, a small species singularly spotted, and Amaryllis Mendelli of fine form and of a rich crimson scarlet colour, and a variety of undoubted merit. A vote of thanks was awarded for the collection.

Mr. Bull exhibited a double white Hyacinth, which is distinct and beautiful. The foliage is stout, short, closely set, and of the richest green; the flowers, which are perfectly double, being pure as driven snow. This is undoubtedly a plant of great value, and merited the first-class certificate which was awarded it. It was introduced from New South Wales, and was named onomiflora flore-plena, its foliage resembling that species, but is of a deeper green.

Mr. Bennett, gardener to M. T. Bass, Esq., M.P., Rangesmore Hall, sent a splendid plant of Phalenopsis Schilleriana, having foliage a foot in length and 5 inches in breadth, a spike 5 feet high with ten branchlets and nearly a hundred blooms. For this superior example of culture the Committee recommended to the notice of the Council that a Davis medal be awarded.

Mr. Herbst, nurseryman, &c., Richmond, exhibited about sixty pots of Lily of the Valley, densely bloomed and very fine; also good plants of Hostia japonica, and was deservedly awarded a vote of thanks.

Messrs. R. Rolleston & Sons, Tooting, exhibited a fine plant of Erica herbacea var., a species of Alsophila from the West Indies, a fine basket of the intense primrose-scented plant Bononia megastigma, and half a dozen plants of Grevillea Preissii, a very graceful Australian plant, not unlike a fine species of Retinospora, with pendulous racemes of flowers freely produced of a soft red colour. This is a very distinct plant, and a first-class certificate was awarded. The plant at first sight somewhat resembles Southernwood or "Lad's Love," Artemisia Abrotanum, clothed with flowers.

Mr. Ollerhead, gardener to Sir H. Peek, Bart., Wimbledon House, had a vote of thanks for two admirably grown plants of Odontoglossum Alexandræ, and he also exhibited a singular flower of the Flaminge Plant having two spathe. These were alluded to in our columns last week.

G. F. Wilson, Esq., F.R.S., sent an Hepatica of a "new colour." It was thought to be unusual by its very red petals, and was highly commended. Mr. Wilson also exhibited an American Goodyera. Some gigantic blooms of Cyclamen persicum were exhibited by Mr. Ware, gardener to — Morgan, Esq., Hungerford Park, Tunbridge Wells, but they were much withered.

A basket of hardy Primroses was exhibited by Mr. B. Dean, Ranelagh Road, Ealing, for which a vote of thanks was awarded. Mr. Chapman, gardener to Dr. Patterson, Northbridge Road, Fulham, exhibited a plant of Phlox maculatus, misnamed Oenothera Sieboldii; and Mr. Douglas, gardener to F. Whitburn, Esq., exhibited a fine head of Poinsettia having nine sub-crowns; it was very robust and good.

ERANTHEMUM PULCHELLUM.

Blue flowers are indeed scarce amongst stove flowering plants, hence are always acceptable, more especially those which flower during the winter months, and one of the most useful is this old, very free-flowering, easily-grown plant. I have plants now in 4-inch pots not more than from 4 to 6 inches in height, little less than all flower, and yet the plants have the healthiest foliage, and are very useful alike for cutting from and for decorative purposes.

I usually cut the old plants, the shoots of the previous year, to within one or two joints of their origin, keeping the plants rather dry for a fortnight after flowering. The plants start away freely and are potted when the young shoots are 2 or 3 inches in length. The balls are considerably reduced, and the plants are returned to the same size of pot, and are given a larger size when the plants have filled the pots with roots. A light airy position is afforded; and if this cannot be given in a house the plants do equally well in a cold pit, admitting air moderately so as to keep up a good temperature; and it is only right to say the plants do better than those grown at a distance from the glass in a warm house, the growth being stouter, shorter-jointed, and the flowering is proportionately finer. From the middle of June to the middle of September they are as well in a cold pit as in a stove.

If bushy plants are wanted the growths may be stopped when the shoots are grown so as to be stopped to two joints; or the plants may have the shoots regulated by tying to stakes as they advance. The unstopped flower earlier than the stopped plants. In April, or when the plants are cut down, cuttings may be taken of shoots with two joints and the growing point, and these inserted in sandy soil up to the second pair of leaves will root quickly in a gentle bottom heat. They should be potted-off singly when rooted, and kept in heat until established, and may be removed to a cold frame in June or July, shifting at that time into 5-inch or 6-inch pots. They will grow very stocky, and flower well in early winter in a cool stove or warm greenhouse, being removed thither by the middle of September.

Cuttings taken in June and inserted round the sides of a pot in sandy soil and placed in a hotbed will speedily be well rooted, and may then be potted-off singly into 4-inch pots, and placed in a cold frame kept close and shaded until the potting is recovered from, and then have moderate ventilation, and be kept duly watered, the object being to keep them dwarf by close proximity to the glass and at a temperature only promotive of slow growth. By the middle of September remove them to a light airy position in a cool stove or warm greenhouse, and in January or February will be a reward of massive heads of blue flowers.

Turfy loam with a third of leaf soil, or preferably a fourth of old cow dung, will grow them well. Weak liquid manure given at every alternate watering after the blooming pots are filled with roots will be found highly beneficial.—G. A.

NOTES AND GLEANINGS.

WM have received from A. D. Hussey Freke, Esq., of Hanington Hall, Highworth, a branch of BLACK THORN, on which a summer shoot has been produced of the extraordinary length of 4 feet 9 inches. It is very slender, and so like an Elm at first sight that we are not surprised Mr. Freke thought it a *lusus nature*. It is undoubtedly the shoot of a Plum, and is so unlike the growth of the Black Thorn or Sloe that the suspicion is it may be a bud sport. We have preserved it, and will have the shoot cut into scions and grafted, for the purpose of ascertaining whether or not it produces fruit of the Black Thorn or of some other form of Prunus.

— THE thirty-third anniversary DINNER OF THE GARDENERS' ROYAL BENEVOLENT INSTITUTION will be held on the 80th of June at the Albion Tavern, Aldersgate Street. Dr. Hogg, one of the Vice-Presidents, will preside.

— A "VISITOR" informs us that the NEW DRACENAS at the Anerley Park Nursery have been operated on by Mr. Bause, who has propagated the tops of the plants "without losing a leaf," and that the colours of many are greatly intensified now that they are no longer seedling but cutting plants. Some plants which did not at the first show colour have recently "broke" into varieties of great beauty. Mr. Wills, we are informed, has had tempting offers made for the collection, but it is not yet decided in what form the plants will be disposed of.

— *YUCCA FILAMENTOSA VARIEGATA* is not only one of the finest of hardy, or nearly hardy, variegated plants, but its beauty is infinitely increased if the plants are grown in heat. The ivory whiteness of the foliage is then most pure, and the leaves in some degree lose their upright habit and recurve in the most elegant manner, rendering it one of the most effective of indoor decorative plants. At the Anerley Park Nursery are some very perfect specimens of this plant, and what is especially noteworthy is the manifest fact that the manager has found out a means of increasing it freely; the stock of this, as of other valuable plants, attesting that not only is Mr. Bause an eminent hybridiser, but is an equally accomplished propagator of plants.

— WM have had forwarded to us by Messrs. James Carter and Co. a collection of blooms of carmine and white-fringed PRIMULAS, gathered from plants which are being grown for seed in their nurseries. These blooms are exceedingly fine, the whites being spotlessly pure, and the darks rich and deep. The individual pipe average 2 inches in diameter, and they are elegantly fringed; but the greatest merit possessed by these flowers is their unusual substance.

— MR. WILLS of the Royal Exotic Nursery, Onalow Crescent, supplied the FLORAL DECORATIONS at the Royal Albert Hall and the Royal box at the state concert. Mr. Wills also supplied the bouquets presented to Her Majesty and the Princesses. Her Majesty's bouquet was composed of Roses, Eucharis, Odontoglossum Alexandræ, Cologynæ cristata, Violets, and Lilies of the Valley. That of the Princess of Wales contained Neapolitan Violets, Dendrobium Wardianum, Lilies of the Valley, and various other flowers. The Princess Beatrice's bouquet comprised various Orchids, Lilies of the Valley, Roses, Eucharis, and Lilac, surrounded by Brussels-lace holders.

— MESSRS. BACKHOUSE & SON state *DAPHNE RUPESTRIS* to be a real Alpine gem, surpassing the well-known *D. cneorum* (the Trailing Sweet-scented Daphne) both in beauty and fragrance. *D. rupestris* has erect shoots, and forms dense compact tufts or carpets 2 inches high, and a foot or more

across, covered with a mass of bloom which sometimes almost eclipses the plant. Its colour is a soft shaded pink or rose, and its flowers are individually larger and more waxy than those of *D. cneorum*, yet forming clustered heads in the same way. *D. rupestris* is essentially a rock plant, growing wild in fissures of limestone in peaty loam. It is perfectly hardy and of easy culture. Its scent is powerful yet very delicate.

— LORD WINMARLEIGH has presented a petition to Parliament from landowners and others in the manufacturing districts, praying for the amendment of the laws relating to NOXIOUS VAPOURS. His lordship alluded to the disastrous effect of the increased discharge of noxious vapours in destroying vegetation, and stated that in some districts the woods in July presented the appearance of trees in midwinter, and land was being rendered gradually valueless. That is no overdrawn picture, as many districts unfortunately prove, and now that minerals are being sought for, and furnaces being erected in many rural districts, legislation on the point is greatly needed. Great injury has already been done to nurserymen and others, and redress is at present an expensive luxury. The Duke of Richmond admitted the existence of the evil, but was not at present prepared to submit a remedy.

— THE *New York Practical Farmer*, in alluding to the approaching Philadelphia Centennial Exhibition, states that the preparations for the HORTICULTURAL EXHIBITION are well advanced. The grounds, containing more than 40 acres, are well laid out in irregular plots for the exhibition of trees, shrubs, bedding plants, &c., which will be furnished by the 150 exhibitors who have already applied for space. In the horticultural building there will be a magnificent display of tender plants collected from all parts of the world. All the native trees of this country will be represented, together with many of foreign origin, particularly the later importations from China and Japan. England, France, Germany, Brazil, Netherlands, Cuba, and Mexico have already applied for space, and so many applications have been made that additional room will be needed to accommodate some special displays. Arrangements have been made for putting up one more building, in which will be shown a very large collection of Rhododendrons from Waterer's of England, and, later in the season, for other displays of like character. Many plants have already arrived, and have been placed in the building; amongst these is a very fine collection of Australian Ferns from Miller and Sievers of San Francisco.

— THE *English Mechanic* says that the well-known Dresden manufacturer, Herr F. Siemens, has recently patented a method of HARDENING, TEMPERING, AND PRESSING GLASS, which appears likely to become of more practical utility than the process of hardening discovered by M. de la Bastie. At the time when the latter's discovery was made public it was announced that Herr Siemens and others had been experimenting in a similar direction, and the accusation was freely made that Bastie's process was being pirated. Whether or not it is so in Germany, the process described by Herr Siemens in his English specification certainly keeps clear of the "claim" put forward by M. Royer de la Bastie, for he does not employ the method of hardening glass by plunging it when heated into a liquid bath at a lower temperature, but hardens the glass by placing it in moulds and pressing it at the same time. The method of Herr Siemens consists in heating and then suddenly cooling the glass to be hardened or tempered.

APPLICATION OF MANURE.

MANY years of experience and observation have satisfied me that the spreading of manure on the surface of the soil, and letting it remain there for some weeks or even months, is good practice, and especially in dealing with light soil. In such soil, if the manure is dug in deeply in the autumn, much of its virtue, I think, is washed into the subsoil before the roots of the summer crops can appropriate the food; in fact I think the food is in a great measure conveyed beyond the reach of such roots.

I have frequently tried the experiment on light soil of digging in a portion in the autumn and leaving another portion covered with manure throughout the winter, digging it in in the spring, and the last-named plan has invariably proved the best. I have not had an opportunity of experimenting on heavy soil. With light old garden soil I am so far convinced that Mr. Graves is right that, had I my manure to purchase and digging to pay for, I should spread the manure on the surface fully

six weeks before digging the ground, and should then choose fine weather for turning it in, planting the crops as soon as convenient after the ground was dug. I should then expect the roots to reach and appropriate the food, much of which, if it had been buried three months previously, would, I should fear, be beyond their reach.

I have arrived at this conclusion solely by the teachings of the crops. I know very little about "science." I would rather have good crops with bad science than good science with bad crops.—A PLAIN GARDENER.

EUPETALUM.

A FIGURE of this plant has been submitted for identification. It is claimed on the one hand to be an Eupetalum, and on the other a Begonia. It is no doubt a Begonia, and the same that is figured and described in vol. xxi. of the "Botanical Register." It is equally an Eupetalum, for Dr. Lindley considered it to be sufficiently distinct to be separated from the Begonias and to rank as a genus—hence he classed it as an Eupetalum. *Eupetalum punctatum*—the only species—and *Begonia petaloides* are synonymous, and either name may be applied to the plant.

It is a pretty stove plant, which was introduced from Mexico nearly forty years ago. It has rosy pink flowers which are freely produced, and the plant is worthy of cultivation. Very recently the culture of tuberous-rooted Begonias has been fully treated on in these columns, and the mode of culture there detailed is suitable for the plant which is now figured.

CAULIFLOWERS AND BROCCOLI.

No. 2.

VEGETABLES of the very first importance are these, and a simple mode of producing an "all-the-year-round" supply of them was described on page 123.

It was there stated as of the first importance to effect a junction of Cauliflowers with the Broccoli in January, and another union of the same nature in June. The cycle is then complete, provided that there is no interruption of the successional crops coming into use in regular order and at the right time.

I mentioned that the supply of these vegetables had been secured by relying on a comparatively few varieties, but I do not mean to suggest by that that only those varieties should be grown. By other sorts than those named the same end can be attained if the selection is carefully made and one is assured that the varieties are true to name. In raising a supply of Cauliflowers it is well not to change the sorts—or the seedsmen supplying them—which prove their usefulness and are ready when wanted. A gentleman will not often trouble himself or his gardener as to the mere name of a Cauliflower pro-

vided it is white, sweet, and good, and not too large; but to have twenty sorts in the garden and none on the table is an unpleasant matter to explain away. I like to grow a few other varieties than those which I depend upon, growing them as a supplementary or experimental crop, taking care to have sufficient of the plain useful sorts which I have proved reliable for a full supply. It should be noted, too, that if these sorts were ordered from another seedsman there is no certainty that they would come as expected. Cauliflowers and Broccoli are very sportive, and they have, furthermore, no fixed and standard nomenclature, but every grower has good stocks. The new varieties are grown and seeded with special care, and may generally be had true for a year or two, but it is surprising how soon their distinctness is lost by being jostled in the crowd; they lose a little here and a little there until they find their level and habitation in the bags of Willcove or Knight's Protecting.

Amongst the new sorts that I have grown I have found Veitch's Protecting Broccoli one of the best of the early section. Heads of this variety will form in the centre of the plant and there apparently remain stationary for weeks. I once went into a garden where the gardener was bewailing his lack of heads; he was, as he said, "in a mess," having no Broccoli. Yet when I assisted him to tear a few plants asunder we found a "hidden treasure." As a late sort *Lauder's Goshen* is an excellent variety, so also is *Carter's Summer Broccoli*. For midseason, or rather late sorts, *Sutton's Perfection* and *Cooling's Matchless* are undeniably good varieties; but I find that more depends on the good name of the vendor than on the names of the seeds.

Broccoli should be grown thinly on hard and rather poor soil, and in a very exposed place. It depends in culture rather than by any inherent virtue of a given kind whether it is "hardy" or not. The plants may be grown hardy or grown

tender according to the treatment they receive. I take but very little notice as to what a seedsman says about this or that sort being "hardy," knowing that the hardihood of the plant does not depend on him, but on my mode of culture. Men fail and blame the seedsmen, but in nine cases out of ten the grower is really at fault by having ordered either a wrong sort or grown it in the wrong way. I sow *Snow's Winter White* and sorts of that class in March, the general crop in April, and the latest sorts as late as June, and by the best selection of sites I can choose I have heads of Broccoli as long as it is possible to have them.

It is more difficult to provide a regular summer and autumn supply of Cauliflowers than a winter and spring supply of Broccoli. A blank must always occur early in July unless a little seed is sown under glass at the present time, and the plants are prepared in warm sheltered positions. It is only

Fig. 43.—EUPETALUM—BEGONIA PETALOIDES.

by this means that the first spring-sown crop can follow immediately on the heels of the crop raised from seed sown in the autumn. I have often found the advantage of planting a portion of the autumn-sown plants on a north border, and so retarding them and obtaining a natural succession from two plantations from the same sowing. I have frequently found that practice to be very valuable, and in fact only by it should I have prevented the blank which is so common—the blank occurring between the maturing of the last autumn and first spring-sown crop which occurs in July. By retarding some plants now and sowing also some seed under glass the blank may be averted, and I am not conscious that it can be prevented by any other means.

The heat of summer is a natural impediment to Cauliflower production. I have occasionally surmounted the difficulty by adopting the trench mode of culture, not only growing the plants, but rowing also the seed in trenches. I had observed that notwithstanding all I could do in watering and surface-mulching that the plants would button and shrivel away—I mean those which had been transplanted—while those remaining crowded in the seed bed and receiving no attention would preserve their freshness as if in mockery of my cultural efforts. Turning the fact to account I have formed trenches similarly prepared as trenches for Celery, and in these have sown the seed very thinly, subsequently thinning out the plants, but not to distances of 2 feet to produce heads a foot across, but thinning only to 9 inches to a foot apart, and obtaining small heads 3 inches in diameter. Those are the heads coveted on a gentleman's table, four of which can be served in a vegetable dish. Huge Cauliflowers I hold to be a huge mistake, involving a waste of space and manure—that is, when they are required for the tables of the educated and refined. I have never failed in the hottest summers to produce sweet serviceable heads by sowing thinly and growing thickly in highly manured trenches, while I have failed completely by the usual mode of transplanting.

For the first sowing I employ Dwarf Mammoth, and for successional sowings I find no sort superior to Walcheren, taking care to have a large supplementary breadth of Veitch's Autumn Giant sown at the same time, and transplanted and grown in the same manner as the general crop of Broccolis, only planting in richer soil. This sort never fails by drought. Thus do I produce a full supply of Cauliflowers and Broccoli "all the year round."—R. FISH'S PUPIL.

CHRYSANTHEMUMS AND THEIR CULTURE— "EXTENUATING CIRCUMSTANCES."

No. 2.

In essaying the culture of Chrysanthemums it is first of all necessary to consider the special requirements of a place or owner. If large blooms are the primary object and the form of the plants of secondary moment, then plants on single stems receiving but little stopping must be grown. These plants for intermixing with the green foliage of Camellias in large conservatories are very effective. Although the blooms are few they are fine, and with care are long-lasting—more so, indeed, than are smaller and more closely crowded flowers.

In order to have very superior blooms the plants should now be established in small pots and be growing sturdily in cool frames; yet fine flowers may be produced from cuttings inserted now, which is the ordinary time of commencing preparations for the supply of these fine autumnal plants.

But any sort of cuttings will not do. An experienced grower knows at a glance which cutting to select. A short-jointed vigorous sucker springing direct from the soil will, with good culture, retain its specially robust habit throughout the season. Weakly cuttings, and especially shoots springing from the stems of the plants, cannot by any course of culture be expected to equal cuttings which come clear from the soil and are stout and strong from the first unfolding of their foliage. After choosing the best cuttings they should be rooted in a cool temperature, having all the light they can possibly endure. Rather than be shaded densely, to prevent flagging they should be sprinkled—dewed frequently, and by no means must they be drawn-up in heat. The cuttings are best potted singly, and a gentle bottom heat of 60° and top heat of 50° will be suitable to a cutting of medium texture. If potted in the autumn they require no bottom heat at all, but if the striking is deferred until spring, and the growth is succulent, the cuttings will damp-off unless afforded brisk heat; they

must, therefore, be treated according to their condition and other circumstances affecting their treatment.

The plants must be shifted as required, and each time before the pots are matted with roots. That is a very important matter, and equally, if not more so, is keeping the soil regularly and continually moist. If the plants in their early, or, indeed, in any stage, are permitted to receive a check by a neglect of potting or watering, no after-attention can atone for the injury which will inevitably follow, however skilful and unremitting such attention may be. To prevent injury by drought the pots should be partially plunged in ashes during the summer, and as near as possible to the water tank. In hot weather the ground amongst the plants should be kept constantly moist, and the plants should be frequently syringed, for if an arid atmosphere is permitted to surround them the foliage, by extreme transpiration, will become exhausted and will shrivel and fall. Syringing the plants occasionally with clear soot water is of great advantage both in fostering their healthy growth and as a preventive of aphid and mildew. Chrysanthemums, as a rule, in the majority of gardens, receive injury by an irregular and insufficient supply of water to roots and foliage during the sultry days of summer. They cannot always have an autumn temperature, but they may be provided with an autumn moisture-laden atmosphere, which is what the plants delight in.

If fine blooms are the primary object, the autumn-struck plants may be topped once, but spring-struck plants should not be stopped at all. But if, on the other hand, shapely plants are required, stopping may be practised as often as is necessary with the large-flowering varieties up to the middle of June, and with the Pompons until July. They may be trained to any form required, and must not be broken by the wind. A site that is sheltered but not shaded should be selected for their summer growth.

When the plants are well established in their blooming pots they must have liquid manure twice a-week until the blooms show their colours (these to be fine must be thinned, leaving the best bud on each point). Soot and cow-dung water is good, varied with guano water at half an ounce per gallon strength, and now and then a pinch of superphosphate of lime sprinkled over the soil and washed in will be beneficial.

The soil should consist of one-half of free loam, one-third of well-decayed manure, and one-third of leaf mould in the early stages of growth; but the final potting material should be of richer loam, substituting manure for leaf mould, using sand in both cases as needed. An admixture of crushed bones or oyster shells is highly beneficial to the plants. Still let it be remembered that those who have many duties to perform ought not to be expected to produce blooms equal to those who make Chrysanthemum culture a speciality, and who devote their whole energies in perfecting their work. Provided a man is able and does his best he is justly entitled to be judged by his whole work and not by a section of it; in a word, it is to him that should be applied "extenuating circumstances."

My visit to London has sharpened me up and taken a little conceit out of me; it has impelled me, however, to greater perseverance, and constrained me to aid others of my calling whose travels are circumscribed by garden walls.—A COUNTRY GARDENER.

DWARFED FRUIT TREES.

MR. SHIRLEY HIBBERD'S paper on fruit-culture read before the Society of Arts will evoke a good deal of adverse criticism, and as I think, very deservedly, for his condemnation of dwarfed trees is too wholesale to be trustworthy. What he should have condemned is the misuse of dwarfing, not its use. I have had sixteen years' experience in growing fruit trees in small gardens situated on the borders of one of our largest and smokiest manufacturing towns. When I commenced fruit-growing I had little or no experience; I had read Mr. Rivers's excellent treatise on "Miniature Fruit Trees," and most of Mr. Errington's articles on fruit-growing which appeared in the *Cottage Gardener*. From my subsequent experience I am, I feel certain, justified in saying that the advice given by both these authorities is perfectly sound, and may be followed (if followed properly) with a positive certainty of success.

I began with a few Apples, Pears, and Plums. With Pears I succeeded from the very first; with Apples I failed at first, but have since succeeded thoroughly; with Plums I have been less successful, but last year my trees bore well, and they are

now fuller of promise than I have yet seen them, and if the season should prove favourable I believe I shall have most satisfactory results to report later on.

The trees I purchased first of all came from a small local nursery. They were badly-grown pyramids; they had apparently been transplanted only once or twice, although they were several years old (I paid 6s. a-piece for them), and consequently bore evidence of being in a state of vigorous growth at the time I bought them. My garden was very poor, and the shock to the Apple trees did them harm as I believe; the Pears, however, seemed benefited by the change, as in two years they began to bear and have gone on increasing in fruitfulness year by year.

My practice from the first was to summer-prune with finger and thumb all the side shoots, but not the leader or the end shoot of the branches. These were stopped in August, and in October or November they were also considerably shortened. In the autumn of the second year I lifted the whole of the trees and replanted them carefully, giving to each some fresh soil. I shortened some of the long straggling roots with a sharp knife, but very little root-pruning was necessary, as the bulk of the roots were nice fibres close at home. The growth the following year was not excessive, and the wood produced was well ripened; while the fruit buds increased in number and a fair crop of fruit was borne, more Pears, however, than Apples, and very few Plums. In the fourth year I removed to another house, and as my tenancy expired in September I was compelled to lift my trees a little too soon (viz., about September 26th), but they were done carefully, promptly replanted in better soil and well mulched. Only one of them suffered; that gave no signs of bearing leaves the following spring, so I wound haybands round the stem, and frequently syringed the head and stem with clean water. It bore no leaves at all the year after removal, but from its appearance I was satisfied it was not dead, and the syringing was continued at intervals till autumn. The following spring it rewarded my exertions by bursting into leaf, apparently none the worse for its leaflessness for the whole of a year. At my new garden, in addition to the trees I have referred to, I planted thirteen more Pears, purchased from Mr. W. Paul, Waltham Cross. These were nice well-trained pyramids when they came into my hands, and as I had gained some experience by my four years' practice I have been enabled to retain them in better form than my first lot. They soon came into bearing; they are now fine handsome trees, studded with blossom buds from top to bottom, and yearly produce me crops of handsome fruit.

My practice has been to lift the trees every two or three years according to the vigour of growth in the preceding summer. Whenever so vigorous as to necessitate the free use of the knife I have lifted them, and always with the result of contracting the growth and causing it to be short-jointed and well ripened, and also always with the result of encouraging the development of fruit spurs. The roots I but rarely cut, except when I find long stragglers. I have also regularly followed the plan of summer-pinching. My trees are all in perfect health, are handsome, and fruitful to such an extent that although my garden is a small one (such as is usual in the neighbourhood of large towns where the freehold is worth £1000 per acre), I have plenty of fruit for the use of my family of eight persons and have some left to give away to my friends. Let me mention that on Sunday last (Feb. 20th) I was able to place on my table seven kinds of Apples and two kinds of Pears all home-grown. My stock of home-grown fruit will last for more than a month to come. As the result of my own experience I can strongly recommend amateurs to disregard Mr. Hibberd's strictures on the system of dwarfing trees, and would recommend a more general adoption of the system properly carried out.—PHILANTHUS.

P.S.—I ought, perhaps, to state that I have now in my garden over sixty pyramids, though some of them have been planted only two or three years.

MANAGEMENT OF PLANTS IN WINTER.

WINTER is generally said to be a time of rest for plants, and no doubt in a general way it is true; but do we always go about the right plan to give plants in pots in houses their rest? and are there not many plants which would be better if they were always kept in a growing state? We may in a rough way divide plants into deciduous (those which naturally cast their leaves), and those which retain their foliage, as ever-

green shrubs and most half-hardy perennials. Nearly all the denizens of our stoves retain their leaves, and are better for doing so. The question therefore arises, Whether it is wise to keep the roots of the plants so dry as is the custom in so many places, while the temperature of the house even at nights is maintained at from 55° to 60°, and in many cases higher?

All deciduous hardy plants in their natural state have their roots more moist in winter time when in a state of rest than at any other time, and I do not believe that the circulation of sap is ever perfectly checked except in the severest weather. If fruit trees are pruned early, and the shoots left on the ground under the trees, there will soon be a marked difference between the plumpness of the buds and bark of those left on the trees and those that are cut off. No doubt some evaporation may take place through the cut, but the greatest part would take place through the bark. Now, in nature the buds and bark of deciduous hardy trees, such as Apples and Pears, Plums, &c., must be kept plump by the action of the circulation of sap. There is not warmth enough or light enough perhaps to cause growth, but there must be a certain supply of sap to compensate evaporation. In fact, if we watch the buds of some of our earlier shrubs, such as Lilacs and Ribes and some of the Honeysuckles, we shall find that there is a constant, though it may be a slow change, taking place in the terminal buds all through the winter. Just as moisture, and heat, and light are the three requisites for the germination and growth of seed, so it is true with regard to all growth, unless we except some of the lower types of fungus, which can grow without light, or plants unnaturally forced in heat, like Rhubarb, Seakale, &c. So long as the roots of deciduous plants are kept moist there will always be a sufficiency of heat and light even in winter to maintain a certain amount of circulation.

I cannot think we act wisely, then, in stoves, where more heat is kept up, to keep the soil in pots dust-dry. Of course many persons will say, Plants must have their rest, and we produce artificial rest by withholding water. I do not want to dogmatise or to lay down any definite rules, because there are such diversities of plants grown in our stoves that they must necessarily require different treatment, but I cannot help thinking that this system of resting plants is overdone. For instance, I have had *Allamanda Hendersonii* constantly growing, blooming from May to December, and the young growth for next year forming before the blooms were off. *Stephanotis floribunda* again, and many other plants, may be constantly kept growing.

No doubt large plants that are overpotted will not require so much water as plants in smaller pots. Still more, too, depends upon the night temperature. If the temperature is low (and it is very wise as a rule during winter to keep the night temperature as low as plants will bear), then less water will be required. Many ornamental-foliaged plants however, as *Crotons* and *Dracenas*, are permanently injured and the foliage lost by not giving moisture enough.

What few deciduous plants there are in stoves may be kept much drier, and, of course, all bulbs that are accustomed to lose all their foliage; but a mistake is often made with many greenhouse bulbs, such as *Agapanthus*, *Vallota purpurea*, *Liliums*, &c., of withholding all moisture during winter. Then, again, to turn from stove plants to greenhouse and bedding plants, here my experience every year more and more confirms my first impressions. If you want to keep healthy *Verbenas* or *Ageratums*, *Calceolarias* or *Geraniums*, you must keep them growing. Of course they do not all require the same degree of heat or moisture. *Calceolarias*, for instance, so long as they have moisture enough require but little heat, but nothing is so fatal as to keep *Calceolarias* dust-dry at the root. I remember seeing an inexperienced gardener at a country parsonage very much astonished, when he told me his *Calceolarias* would damp-off however dry he kept them, at my calling for a tub of water and putting all his plants overhead in it. *Verbenas*, again, as a rule are kept far too dry, and *Ageratums* too cold. And that much-enduring plant, our old friend the zonal *Geranium*, what a variety of treatment and suffering he has to go through—either with roots dust-dry in small pots on dusty shelves near the roof, or delegated to cold frames with all the leaves picked off, and nothing larger than a shilling allowed to remain on the plant. Sometimes, no doubt, the cold-frame treatment may be a case of necessity; but how often I am told they must not be kept growing during the winter for fear of the growth being premature, or of their

beginning to flower too soon, or of their being made too tender. And then with regard to the poor unfortunates with dry roots and flagging leaves on shelves; they are not watered because I am told bedding plants do not want water in winter, it would unduly excite them.

I have now for several years carefully tested the fact whether plants kept growing all the winter and put out in May in full bloom, last any less time in bloom than those which have their growth and then their blooms to make. I have kept Geraniums in bloom on shelves in a stove all winter, and found they bloomed just as freely in the summer; and certainly I have always found the beds of Geraniums which were in fullest bloom when I put them out first filled the beds with growth and bloomed best afterwards, and will last in bloom quite as long as those that come into bloom later. In fact, at taking-up time, except that the plants may be bigger, there will be no difference as to the number of blooms. Of course, a zonal Pelargonium is an exceptionally free-blooming plant, and (so long as it grows well), provided it does not overgrow, it will continue to bloom.

It is not equally true of Lobelias or Verbenas that if put out in full bloom they will continue to bloom the whole season. Still it is equally true that they do not require much rest in winter. Verbenas should be kept growing, but the growths should be pinched back so as to make the plants bushy. Lobelias, again, want the flowering shoots pinching out; but the great advantage of a tolerably warm treatment of these plants during the winter is that it enables persons in spring to make much larger and better plants. I know I shall be told it is not everybody who has the means to give bedding plants this treatment, and that they are not worth the trouble, and so on. Better go back to good old perennials and mixed border plants that gave one no trouble except tying-up, or dividing the roots, or digging over the beds, &c. Well, if bedding-out is worth doing it is worth doing well, and I am very sure that the good taste of the public will not long stand the geometrical arrangement of mere ornamental foliage in flat formal patterns and beds.

If a garden can be made gay from June to November with a proper selection of flowering plants, and if care is taken by means of Alpine plants, and bulbs, and other spring flowers to make the garden bright in the spring months by hardier plants, I am confident that the best strain of bedding plants will still retain their ascendancy, and that the proper winter management of them will still be of great importance. I know in many cases they are kept cold and neglected on the makeshift principle, when vineries might be utilised without any detriment to the Vines. And are not, again, gardeners placed too much under the dominion of their Vines? Why should it be thought the one thing requisite in gardening to be able to produce a bunch of Grapes at table all the year round? And are they worth all the trouble and expense they give? I know it is a bold thing to say anything against Grapes and Vines, but I am free to confess that I often think they are the worst things a lover of flowers has to contend with. You may in happy England see miles upon miles of houses given up to nothing but Vines. "Sacred to the Roots" is written on the borders; "Sacred to the Leaves, and Stems, and Fruit" is scored up in the house. And if one ventures to suggest that the houses might be utilised for plants as well—"Oh, no!" one is assured; "the two things are quite incompatible." Partridge is a good thing, but one even tires of *toujours perdrix*; and I should myself get heartily tired if I always saw a bunch of Grapes at table. I am afraid, however, this is a digression which will call down the righteous wrath of many a Vine-grower. In speaking of the winter management of plants in houses I wish I could see a little more use made of vineries, and that there was not such a tendency to give artificial rest by means often injurious to the plants.

These remarks are, I fear, somewhat discursive and hastily written, but they will answer their object if I induce some of your correspondents to still further ventilate the subject and give us the benefit of their experience. What I maintain is, that many stove plants are kept needlessly dry at the roots with too high a night temperature; that many of our greenhouse plants are kept, on the other hand, too cold; while our bedding plants are crippled and suffer during all the summer, or at all events till they have their roots and fresh growth established, because they were starved and neglected during winter. The object seems to me more just to try and keep life going, not to keep it vigorous and healthy; and I feel sure with our present improvements in our means of heating, light, and ventilation,

there is no reason why plants should be an eyesore during winter rather than a pleasure.—C. P. PRACH.

EARLY WRITERS ON ENGLISH GARDENING.

No. 10.

REV. SAMUEL GILBERT.

EARLY in the seventeenth century the gentry of England began to write on its gardening. Dr. Beale, Evelyn, and Sir William Temple are instances, and the gentleman I am about noticing was one of the number. Of the birth and parentage of Samuel Gilbert I have not been able to discover any particulars. That he was Rector of Quatt in Shropshire, and Chaplain to Lady Jane Gerard, Baroness Bromley, is stated on the title-page of his little volume entitled "Fons Sanitatis, or the Healing Spring at Willowbridge in Staffordshire." This

Fig. 44.—Rev. Samuel Gilbert.

was published in 1676. It was printed for the author, which sustains the statement in Harwood's edition of Edswick's "Antiquities of Staffordshire," that Gilbert was a physician, and the book might be intended to increase the number of his patients. The clerical and medical professions were then and until the end of the last century very frequently and usefully combined. If they had not been so combined villages distant from a town must have been almost excluded from a doctor's assistance. He glances at this in his "Fons Sanitatis." At the end of each list of cases cured by the Willowbridge water verses are inserted in which he especially warns against those unskilled practitioners

"That speak most honey-healing words to please you,
Who of your money not your pain will ease you."

His verses are distributed through all his works, and those in Rea's "Flora" seem to be from his pen, but are only one evidence among many that he was entitled to the designation engraved beneath his portrait—"Philomusus," a Lover of Learning.

He dates his "Florist's Vade-Mecum" "at his house in Kinlet parish, near Bewdley in Worcestershire." This was in 1688, and his father-in-law John Rea had been residing with him; for Rea dated his "Flora, Ceres, and Pomona" in precisely the same terms in 1676, adding, "It is a rural desert where it was my unhappiness to plant my stock."

Mr. Rea died in the November of 1681, and his will states that he lived in a tenement at Kinlet, rented from one Oldnall. Rea devised this to his daughter Minerva, wife of Samuel Gilbert, with remainder to her issue, who Rea describes as his grandchildren. There was one grandson, Arden Gilbert, and four or five grand-daughters, and among these he left the profits arising from lands he leased from John Woolriche, Esq. To his friend Thomas Bray of Worcester he devised such of

his plants and flowers in pots as might be approved by the above-named Minerva, but to leave sufficient of each kind to keep up the stock. To Thomas Tassell of Wyche he bequeathed his Tulips. Of these Mr. Gilbert observes, "Mr. Rea had the largest collection of any man in England, some of which I lost by being beyond sea at his death."

Rea planned the gardens of Gerards Bromley, the seat of Lord Bromley, a title now extinct, and in the dedication to the young lord of his "Flora, Ceres, and Pomona" he says, "A little time may possibly produce such a garden as Gerards Bromley, when you shall be pleased to accomplish what was there begun by your noble father."

The publication entitling Mr. Gilbert to a notice in these pages is "The Florist's Vade-Mecum." This was published in 1683, and other editions unaltered, though said to be "enlarged," in 1693 and 1702. Bound with it, and mentioned on the title page, is "The Gardeners' Almanack for five years, 1688-1692." With monthly directions what ought to be done in either kitchen or flower garden for ever." The monthly calendars have specified the signs of the zodiac influencing the days, because at that time gardeners were guided by such directions as this which he announces: "If you prune your Vines the moon in full, and posited in Taurus, Leo, Scorpio, or Sagittary, neither worms nor birds will infest your Grapes." Yet it is a good directory in floriculture. Appended to it is a "Treatise of Auriculas," of which he and others were great patrons, as is told in this paragraph of its introduction: "Peter Egerton of Boughton near Chester, Esquire: I cannot but let every lover of flowers know his remov'd abode, to his estate at the Hall of Shaw, near Manchester in Lancashire, where he will keep up (and increase as new faces appear) his choice collection of plants and flowers. The last April I waited on him, before he removed from Boughton, and there found many Auriculas, that were not mention'd in this Compendium, and also three or four that I afterwards saw in the Pallace Garden at Worcester, belonging to Mr. Thomas Newton, gentleman to my very good lord, the Right Reverend Father in God, James Lord Bishop of Worcester. So that from Mr. Egerton's collection, who was the best florist in Cheshire, and hath the same pre-eminence in Lancashire, and Mr. Newton, who may challenge the same for skill in Worcestershire, and myself in Shropshire, and consequently from the choicest collections in these nations, I desire you accept the ensuing catalogue of the best single striped, double, and double striped Auricula's."

Of the date of Mr. Gilbert's death I have no information. There are no records of his will. Letters of administration were granted to the estate of a Samuel Gilbert in March, 1692, but I have no evidence that he was the author of "The Florist's Vade-Mecum."

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 24TH.

THE adjourned Annual Meeting of the Fellows of the Royal Horticultural Society was held in the Council Room, South Kensington, last Thursday, under the presidency in the first instance of Lord Alfred Churchill, and subsequently of Lord Aberdare, President of the Society. The object of the meeting was to reconsider the privileges of the Fellows for the year 1876, a committee consisting of Mr. Hardcastle, Mr. Wilson, Mr. Freahe, Dr. Pinches, Mr. Grote, and the Hon. R. W. Oshetwynd, having been appointed at the meeting of the 10th inst. to confer with the Council with respect to this question. The result of the conference between the Council and the Committee was the compilation of an "Amended Summary of the Privileges of Fellows for the year 1876." The Summary, copies of which were circulated in the room, was as follows:—

"**AMENDED SUMMARY OF THE PRIVILEGES OF FELLOWS FOR THE YEAR 1876.** Admission fee, two guineas. A. *Two-Guinea Fellowship.*—Each two-guinea Fellow is entitled to one non-transferable ticket, giving admission to its owner on all occasions, with liberty to introduce personally two friends, except to fêtes, conversations, and flower shows, and on reserved occasions. B. *Four-Guinea Fellowship.*—Each four-guinea Fellow is entitled to two transferable tickets, admitting the bearer on all occasions, with liberty to introduce personally four friends, except to fêtes, conversations, and flower shows, and on reserved occasions. C. *Six-Guinea Family Ticket.*—Two-guinea and four-guinea Fellows, by raising their subscriptions to six guineas, will be entitled to receive, in addition to the privileges of four-guinea Fellows, one extra transferable ticket, giving admission to the bearer on all occasions; and, except to fêtes, conversations, flower shows, and reserved occasions, to the whole of the owner's family resident in his house, including necessary attendants not exceeding two. On promenade days nurses will not be ad-

mitted, and children under twelve years of age must be accompanied by their parents or grown-up member of the family. D. *Twenty-Guinea Life Fellows* to have the same privileges as two-guinea Fellows; and *Forty-Guinea Life Fellows* to have the same privileges as four-guinea Fellows. E. *Twenty-Guinea Life Fellows*, by paying two guineas annually, may obtain the privileges of four-guinea Fellows. F. The privileges of holders of ten-guinea tickets remain unaltered. G. To all classes of Fellows the following privileges: 1. To purchase for members of his or her own household, at the price of £1 1s. each, non-transferable tickets, which entitle the nominee to all the privileges of personal admission that Fellows themselves possess, except that of admission on specially reserved occasions. 2. To purchase, for £1 1s. each, books containing twenty-one orders of admission to the promenades (for admission to which no money shall be taken at the gates). 3. To purchase, for £1 1s. each, books containing forty-two orders of admission on all days, except shows, fêtes, conversations, promenades, and specially reserved occasions. 4. To admit, by personal introduction, friends to the Gardens at South Kensington on Sundays. 5. To admit friends daily (Sundays excepted) by written order to the Gardens at Chiswick. 6. To purchase, previous to the day of each show, tickets at reduced prices. 7. To obtain, upon application, such seeds, plants, and cuttings as the Society may have in sufficient numbers to meet the Fellows' applications. 8. To purchase the flowers, fruit, &c., grown at Chiswick, which may not be required by the Council for scientific purposes. 9. To receive, on application in writing, a copy of the publications of the Society. 10. To vote at all meetings of the Society. 11. To give notice in writing of being relieved from the yearly payments while resident abroad. 12. To free admission to the reading room and Lindley Library. Non-transferable tickets at 10s. 6d. per annum, admitting to all shows, scientific meetings, and lectures of the Society (but not to promenades nor on reserved occasions), and to the Chiswick Gardens on week days, will be issued to *bond fide* gardeners recommended by two Fellows. All former Fellows of the Society who have withdrawn therefrom, and who shall have paid all subscriptions due from them to it, will not be required to pay a fresh entrance fee if they shall be re-elected in the year 1876."

The meeting, which was not very largely attended, differed as regarded the conduct of its proceedings from, it may be said, all the public meetings of the Society held during the past three years, inasmuch as there was an almost complete absence of the contentious spirit which has invariably pervaded the discussions at the meetings held in the time indicated. Both at the Council table and in the body of the room an anxious desire for harmonious action was manifested, which resulted, as might be expected, in a satisfactory termination to the day's proceedings. The members of Council present were, besides Lord Aberdare and Lord Alfred Churchill, Sir Trevor Lawrence, Bart., M.P.; Colonel R. Trevor Clarke; Mr. Henry Webb (Treasurer); Dr. Hogg, F.L.S. (Secretary); Dr. Denny; Mr. W. B. Kellock, F.L.S.; Mr. Robert Warner, F.L.S.; Mr. Wm. Haughton, and Mr. F. Campton. Amongst the general body of Fellows present were Sir Henry Thring, C.B.; Dr. Pinches, Mr. J. A. Hardcastle, Mr. Godson, sen., Mr. Alfred Smee, Mr. G. F. Wilson; Mr. Edgar Bowring, C.B.; Mr. H. Liggins, Mr. S. Hibbard, Dr. Masters, Sir Peter Pole, Mr. West, Mr. Richard Redgrave, &c.

THE CHAIRMAN (Lord Alfred Churchill), in opening the proceedings, said that in the unavoidable absence of the President of the Society, Lord Aberdare, he had been requested by his colleagues on the Council to take the chair until such time as the President should arrive. The amended summary of the privileges of Fellows for the year 1876 was circulated in the room, and he presumed that each Fellow was supplied with a copy. He might remark that Lord Aberdare was most anxious to address the meeting on the amended rules, as the subject was one in which he took the liveliest interest, and his Lordship hoped to be present before the meeting was brought to a close [hear, hear]. The previous policy of the Council had been characterized as a policy of restriction, but their present policy, illustrated by the proposals involved in the amended summary of privileges, was one of concession, for it was felt by them that by treating the Fellows liberally the Society would be more likely to obtain their support, and thus insure for it a career more prosperous than its past one had been. At the present time there was a greater necessity than ever for harmony amongst the Fellows [hears], because the income of the Society had been diminishing for several years past. Under ordinary circumstances the rent of the gardens should have been paid this year; but the fact was the Council had not the means of discharging the rent, and accordingly the Royal Commissioners had given them three years more of grace in order that the Society might be enabled, by means of certain alterations, to raise their annual income to £10,000. Their income was little more than £7000, and up to the present time this year they had only received £3000; but of course the year was yet young. It was to be hoped that those who were now being liberally treated would come forward and aid the Society with their subscriptions [hear, hear], and that the plan now proposed would have the effect of bringing a very large addition indeed of numbers to the Society, and consequently a proportionate increase of funds [hear, hear]. The Society's trade debts were heavy, but if the proposals now submitted by the Council to the Fellows were received by the latter in a generous spirit and loyally supported by them, the Society would be able to borrow money sufficient to discharge those debts, and to place it in a more flourishing condition than it occupied hitherto [applause]. It should be clearly understood that if they failed at the end of three years to raise the income of the Society to £10,000 annually the Society could not exist any longer, and

* The Council reserve power on four occasions annually to have receptions, at which non-Fellows and bearers of their transferable tickets shall have a right to be present without special invitation.

the Council certainly would not be justified in incurring expenses they should not be able to meet [hear, hear]. He should like to refer for one moment to the privilege lettered C in the amended summary of privileges. It reads thus:—"Six-guinea family ticket.—Two-guinea and four-guinea Fellows by raising their subscriptions to six guineas will be entitled to receive, in addition to the privileges of four-guinea Fellows, one extra transferable ticket, giving admission to the bearer on all occasions; and, except to fêtes, conversazioni, flower shows, and reserved occasions, to the whole of the owner's family resident in his house, including necessary attendants not exceeding two." Now, he confidently submitted to the Fellows that that rule, besides being a conservation of old privileges, made an addition of new ones which he doubted not the Fellows could not fail to appreciate [hear, hear]. Turning to the condition to which the Society had been brought, the noble lord said if he were asked why it was that the Society had not risen to a state of prosperity, he should answer that it was to be ascribed to the schisms and the dissensions which had for some years racked the Society and placed it in a most unfortunate position [cries of "hear"]. And now, when there was the prospect of a better state of things, he confidently asked, and he felt his appeal would not be in vain, that at this critical juncture in the life of their Society there should be unanimity amongst the members [cheers]. They had before them the munificent offer of Mr. Freake to lend a large sum of money to extricate the Society from its difficulties; but he would remind the Fellows that even that munificent act would not of itself have the desired effect unless the members of the Society were unanimous in their action [hear, hear]. That fact he felt he could not too strongly impress upon the minds of the Fellows; but he was fully assured that at such a time—with interests dear to them all at stake—with the fair chance of bringing round the Society to that position of independence and usefulness which in this great community it ought to occupy, with the fact before them that they had been met by the Royal Commissioners in a liberal spirit, and that through the voluntary action of the Commissioners they had obtained a very fair and reasonable time to pay the rent of the gardens, the Fellows, sinking all minor differences, would work earnestly and well for the attainment of that desideratum which could alone save the Society—the raising of its income to £10,000 a-year [cheers]. After all that would not be so difficult of accomplishment if only the Fellows gave a loyal and a persistent support to the Council, who would leave no stone unturned to bring about a prosperous condition of the Society [applause]. In conclusion of his remarks the noble lord observed that for Fellows in or joining the Society there was no personal responsibility beyond that of their yearly subscriptions [cheers].

MR. ALFRED SMYTH.—I apprehend, my lord, that the great thing for us to do on the present occasion is to settle the question of the reception of the annual report of the Council [cries of "no, no"].

A FELLOW.—Oh, that has been done [hear, hear].

THE CHAIRMAN (Lord Alfred Churchill).—I may say the report of the Council was accepted by the Fellows at the last meeting; and after that was done Lord Aberdare rose and said to the meeting, "If you like to appoint a committee to confer with the Council on the question of the privileges of the Fellows for the year 1876, this is the time to do it;" and this amended summary of the privileges is the result of the conference which has taken place [hear, hear].

MR. A. SMYTH.—I thought it was prior to that Lord Aberdare made that statement.

THE CHAIRMAN (Lord Alfred Churchill).—Not at all; it was exactly as I have told you.

DR. PINCHES observed that he had so often found himself in opposition to the ruling powers of the Society, that he scarcely knew how to speak on the present occasion when he had the almost previously unknown happiness of not being in opposition [cheers and laughter]. Briefly he would say that it might probably be within the knowledge of the Fellows that at the meeting of the Society last December, after a very long and important discussion, he had felt it his duty to move an amendment to the propositions which were then submitted by the Council with respect to the privileges of the Fellows of the Society; his amendment being to the effect that the Council should be asked to reconsider the regulations respecting the privileges of the Fellows of the Society for the year 1876. And in doing that he expressed his regret that the Council of the Society, in putting forth the revised code of privileges, did not submit them to the Fellows for an expression of their opinion upon them [hear, hear]. His Lordship in the chair seemed to be in some doubt as to the fate of the amended summary of the privileges now submitted by the Council to the Fellows of the Society. He (Dr. Pinches) was of opinion, however, that the general desire was to elicit the opinion of the Fellows as to the desirability of receiving and approving these amended regulations or not [cries of "hear, hear"], and to express an opinion that the Fellows should be glad that the Council was fully prepared to carry out

the amended regulations [hear, hear]. One could easily understand in dealing with the affairs of a Society placed in so unfortunate a position as theirs was that some means for mending the position of the Society would be sought for; and it certainly was not unnatural for the Council to suppose that there had been an abuse—and it was a very fair interpretation—with respect to the transfer system of tickets, to suppose that it was not calculated to induce those who were not Fellows of the Society to become so [hear, hear, and cheers]. But he was sorry it had not occurred to the Council that they had overlooked one very important feature in the case, which indeed he had overlooked himself, as he had not known it himself, and that was the fact that there were many gentlemen—indeed ladies and gentlemen—who had paid considerable sums of money for certain privileges and made a contract with the Society for their enjoyment when they, no doubt, thought the Society would exist in perpetuity [hear, hear]. And again, he was reminded that the life Fellows, and ladies and gentlemen living at places remote from these gardens, felt that if they had not the power to transfer their tickets they had in fact paid twenty guineas or forty guineas for nothing whatever [applause]. That was a point which the Council had overlooked, and which he himself had overlooked. Well, that point being disposed of, they had to consider whether the new regulations did contain the germs of a satisfactory basis, or did they contain everything the Fellows could reasonably expect to have. That was, or rather these were, the questions the meeting had to consider [hear, hear]. There was no question whatever that the Fellows had preserved to them all the privileges they had hitherto enjoyed in their integrity; and in addition to these there was a most important, and to his mind valuable, concession in the clause lettered C [hear, hear]. If they were to expect an accession of Fellows to raise the resources of the Society, they must look forward to a large number of householders in that wealthy and populous neighbourhood joining the Society. One of the difficulties with which they were obliged to deal was a disinclination on the part of members to remain in the Society because they had to pay a considerable sum of money for the enjoyment of very few advantages as far as their families were concerned. But now a forty-guinea Fellow can bring in six Fellows in this neighbourhood, which seemed to be fruitful in the production of large families [a laugh]. In it every householder had at least three or four nurserymaids, and perhaps six, or eight, or ten children [laughter] who could now avail themselves of the advantages of the gardens; and by a family ticket not only the heads of families would be admitted, but admission was given to individual members of families, who were unable always to have the opportunity of coming to the West End, by having separate tickets. In addition to that there was a feature which had existed in all the regulations of the present Council—that was in No. 1, by which a Fellow may bring in members of his family. So the meeting would observe that, besides the conservation of the privileges the Fellows enjoyed anterior to the promulgation of the last paper, they had the advantage of procuring a family ticket for six guineas, and besides the advantage of buying other tickets at a reduced cost [hear, hear]. What, then, were they doing with respect to subscribers? They would no longer have those pretty little books of tickets which would fetch a round sum of money as waste paper [laughter]. They were of little use now, because the last Council did certainly restrict the privileges attached to these tickets in so far that they were not available on promenade days. It was the intention of the Council to restrict them in that way. They had asserted a perfectly unimportant principle, but they would have the advantage of a more select assemblage in their gardens [hear, hear], because no one was to come in by payment, but any Fellow could bring in anyone who called on him by buying a book of twenty-one tickets [hear, hear]. He had endeavoured to place before the meeting the debtor and creditor side of the account, and the advantages seemed to him to be all very much in favour of the Fellows. Could anyone deny that some concessions might be reasonably asked of the Fellows in the face of the difficulties which beset the Society? [hear, hear]. The abandonment of these tickets was one of a most trivial character [hear, hear], and there was not one they could more reasonably ask for. The fact remained—they must raise the income of the Society, and they all knew that a "house divided against itself must fall." He did believe most sincerely and honestly that one reason why the fortunes of the Society had not risen as they ought was the multiplicity of divisions and schisms which had racked the Society to pieces [loud cheers]. If the Council has been wise enough and good enough to take earnestly and seriously into consideration the difficulties in which the Society was placed, the Fellows in return should meet them in the same spirit and adopt the suggestions placed before them with perfect unanimity [applause]. Because, it seemed to him, that whether the Society was saved or not was a moot question, but there could be no doubt the Society must be relieved from its difficulties, and that could only be done by the motive and anxious desire to bind themselves all together for the benefit of the Society [hear,

hear]. A critical question was impending over them. They had less than half the funds they should have because the dissensions hitherto existing in the Society had operated most injuriously in a quarter where they looked for munificent aid; he referred to the proposition of Mr. Freake to advance the Society £5000 or £7000 to extricate it from its difficulties. Of course Mr. Freake, like any man of sense, hung back as to his venture because he did not know what the Society was going to do, and saw the whole concern was being pulled to pieces; but if they went before the public with a scheme, and exhibited unanimity with respect to it, he had no doubt that would have so great an influence on Mr. Freake that he would no longer hesitate to do what he promised [hear, hear]. He must say the action of the Council in this case met with his entire approbation, and entitled them, not to his thanks, but to the thanks of every Fellow of the Society. If the adoption of the proposals had been moved he should be happy to second it [cheers].

Mr. ALFRED SMEE said he believed the true policy to be pursued was to get all parties together, so that they might act with unanimity. He begged, however, to state most emphatically that nothing that all of them could do could damage the Royal Horticultural Society [hear, and a laugh]. Although the Society might be short of funds, or that it had gone down in its funds, the Royal Horticultural Society still would rise [hear and "question"]. The Society could never receive any injury, but while they were saddled with creditors they must provide the necessary means to pay them [hear, hear]. How were they to keep up their expenses? This summary of amended privileges would not bring them out of their difficulties. It never would do that. Even if they did not support their Society it would still remain as it was [laughter]. They must fall back upon some method by which to increase their income. Let them look at the Alexandra Palace and other places of amusement. They might have skating rinks and ice places, and he should be happy to inquire how they could have ice winter and summer. Still, however, they might introduce novelties. Unless they kept up their horticulture they should never maintain their gardens or their position [hear, hear]. He again asserted that nothing could damage the Royal Horticultural Society in itself. The question they had to decide was, how, under their present circumstances, they proposed to go on until final arrangements were made, so that the Society might go on prosperously.

Mr. HARDCASTLE said he wished to express on his own part—and he did so quite personally, although he dared say all the other members of the committee appointed to confer with the Council agreed with him—his great satisfaction at the step the Council had taken that day [cheers]. He did not say that satisfaction was qualified by something which fell from the chair, but at any rate he could not take more than his just share of responsibility for the action of the committee. As far as he understood these regulations, they appeared to be founded upon an exceedingly good principle, although possibly some of the details might require amendment. The Council had adopted, and in fact must adopt them on their own responsibility [hear, hear, from members of Council]. Of course, the Society was only too glad they should take the responsibility, the Society being convinced at the same time that the regulations were based upon highly honourable principles [hear, hear]. He might be permitted to state what perhaps was known to most ladies and gentlemen present, that as far as he had had the opportunity of studying the regulations, they were substantially what were submitted by one member of the committee to the Council, and to him whatever credit can be given was due to him for having devised these regulations [hear, hear]. He (Mr. Hardcastle) did not wish to criticise them, because he thought that in the second section there was mention made of the "owner" in this way:—"Each four-guinea Fellow is entitled to two transferable tickets, admitting the owner on all occasions, with liberty to introduce personally four friends, except to fêtes, conversations, and flower shows, and on reserved occasions." Now in that section they had the word "owner," and —

A FELLOW.—It means "bearer" or "holder."

Mr. HARDCASTLE.—Oh, of course there is no doubt as to what it is meant for.

The CHAIRMAN (Lord Alfred Churchill).—The word in the printed list is a misprint.

Mr. WILLIAM HAUGHTON.—That is so; it is a misprint.

Mr. HARDCASTLE.—Very well; but it would be as well perhaps to have a qualified admission for servants up to a certain hour of the day; but I must say, as regards the other regulations, they appear to me to be based on a right principle. I will not take up the time of the meeting any longer, because I have just seen a friend of mine (Mr. Edgar Bowring, C.B.) getting on his legs. I hit down saying that I trust the meeting and the Society generally will accept these regulations unanimously [cheers]. I think, my lord, it is most important that if these regulations are accepted at all they should be accepted unanimously [applause]. By adopting such a course we should prevent the recurrence of those dissensions which have unfortunately too

long prevailed in the deliberations of the Society, and which, I am not without hope, will eventually cease to be one of the features of the proceedings of the Royal Horticultural Society [cheers].

Mr. EDGAR BOWRING, C.B.—I think it would be much the best course if the Fellows agree with my suggestion that the meeting should first approve of the proposed regulations which the Council has submitted to the Fellows [hear, hear]. I shall be very happy to second the adoption of these regulations if any gentleman moves it.

Dr. PINCHES.—I will move the adoption of the regulations with much pleasure [hear, hear].

Mr. BOWRING said he was glad the motion had been proposed by Dr. Pinches, and thought the few words he (Mr. Bowring) had to address to the meeting would be found of a highly satisfactory nature. He had to state that on his way to that meeting he met Mr. Freake, who said he was sorry he had not known the meeting was to have been held. Mr. Freake authorised him to state on his behalf that without considering these regulations *per se*, if the meeting adopted the propositions of the Council, if there were no differences of opinion upon them or unnatural dissensions amongst the Fellows, he was still prepared to carry out his munificent offer of advance of money to the Society [loud cheers]. On that point he might say no more [hear, hear]. He entirely concurred in the opinion that unless something was done to place the Society on a proper basis they should lose a number of their country Fellows and their London Fellows as well, while very few fresh Fellows would come into the Society. He was very glad, therefore, to see the way in which the Council had come round to the views of the Fellows. He would most earnestly urge upon the Council and upon all the Fellows that it was of the very greatest importance to recover the Fellows they had lost [hear, hear]. He had every reason to know that most of the Fellows left the Society because of the loss of their privileges, which left their membership of no use whatever to their families. Let the Council make a special appeal to these Fellows. He should make the suggestion that a gentleman should be appointed to go round to those Fellows and bring them back to the fold of the Society [hear, hear]. As to getting an accession of fresh Fellows, he thought they should take some strong and immediate steps to induce people to join the Society. He should say there ought to be a systematic house-to-house canvass in the interest of the Society in that great, wealthy, and growing neighbourhood. He need not detain the meeting with any further remarks. He saw every appearance of perfect unanimity on the questions before them, and he felt very happy in seconding the motion proposed by Dr. Pinches, that the propositions of the Council contained in the Amended Summary of Privileges of the Fellows for the year 1876 be adopted by the meeting [cheers].

Sir HENRY THRING, C.B., said he was extremely happy to see the meeting unanimously in favour of the reception of these rules. When the Society did come down, come down they must [cries of "no"]. Well, he wished to explain shortly what a society like theirs was. On various occasions he had heard gentlemen call themselves the "South Kensingtonian" and the "Horticultural" party respectively, who never had anything to do with the meetings of the Council.

[Lord ABERDARE, the President of the Society, here entered the Council-room and took the chair, which Lord Alfred S. Churchill vacated as soon as the noble President was seen approaching the Council table.]

Sir HENRY THRING, in continuation of his address, said they had heard the Society could not exist unless under the Charter. He pledged his legal reputation it was not possible for it to do so. They should all like to see the Horticultural Society rise like the phoenix from its ashes, but they were anxious to see how that could be accomplished. Some twenty years ago the Society chose to accept a fresh charter, and that was the one under which it existed. It possessed in South Kensington a garden, whether for good or bad, but at any rate the garden at Chiswick was the property of the Society. The Society must remain in unity or cease to exist [hear, hear]. It must retain both gardens. There was no law by which one party in the Society could call itself the "Royal Horticultural Society" and the other the "South Kensington Society." He pledged his legal reputation to the meeting that under the Charter they could not separate their gardens. What would be the effect of all this quarrelling? They had three different Councils in office during the last four or five years. The first Council was turned out for some reason or other; another came in which was not very flourishing, and the Society became in a worse position still. He did plainly assert they were on the verge of ruin [no, no]. Let them look boldly into the future if they wanted to have a brighter prospect for the Society. Let them have a house-to-house canvass [hear, hear]. Every man must exert himself to save the Society. When he first came to that neighbourhood eleven years ago the Society had an income of £7000 a-year. They must all pull together, and not come there to talk a lot of balderdash [oh, and laughter]. It was not a

question of science at all, it was a question of money [hear, and laughter]. Unless they could raise their income to £10,000 annually in three years' time the name of the gardens—horticultural science and all, would be gone [cries of "never" and some laughter]. Well, perhaps they would let him turn for a moment to the privileges which they either must pass or must liquidate like any bankrupt society, and have their property sold, their flowers sold, and their name destroyed. A great deal had been spoken about the Royal Commissioners. He was not himself a Commissioner, but they were told the Commissioners had not done this or done that, but the Commissioners had given their ultimatum. The Commissioners were a public body who would not sacrifice their property unless for the purposes of advancement of science and art. It could not be tolerated that scientific horticulture was to be abandoned [cries of "hear"]. The two must go together or cease to exist. Well, what was the ultimatum of the Commissioners? It was that the Society was to raise its income to £10,000 a-year. Why was that? Because without that amount of income the gardens must be given up. The fact was the Society was on the very verge of ruin—on the very verge of bankruptcy [cries of "no" and a voice "hear"]. They wanted to raise £10,000 a-year, and they wanted everybody to endeavour to persuade his friends to help them in their very great and very palpable difficulties. He must say that the Society, or at least the Council, might have expressed an opinion that it was not intended by these new regulations that people should give their next-door neighbours tickets of admission to the gardens.

A FELLOW.—Oh, not at all [hear, hear].

SIR HENRY THRING.—Well, then there ought to be an honourable understanding that these tickets will be given only to those people who cannot afford to pay for admission to the gardens [oh, and symptoms of impatience]. In conclusion of his address, which was listened to with manifest signs of disapprobation and impatience, Sir Henry Thring said that if anything fatal happened to the gardens the splendid property of the neighbourhood of South Kensington would be seriously damaged [hear, hear].

MR. SHIRLEY HIBBERD said the country Fellows of the Society would undoubtedly be glad—in fact delighted, to hear that there was at last a prospect of peace being restored [hear, and oh]—yes, restored to the Royal Horticultural Society [hear, and cheers]. It was only with the case of the London Fellows that any difference might be expected. It would be as well that they should be all ready to join together, heart and hand, for the benefit of the Society; but it would be as well to know the conditions or the considerations out of which the troubles arose, and which brought about the amended summary of the privileges for Fellows for the year 1876.

MR. HENRY LIGGINS.—Bygones ought to be bygones [loud cheers].

MR. SHIRLEY HIBBERD.—I think so too [laughter]. He went on to say, that while he should not criticise this amended summary, he would say that on the 9th of December when the question of these privileges was discussed at some length—indeed at very considerable length—not one of the country Fellows offered any opinion upon it, and he was really very glad that the case was the same to-day. He had his own doubts as to the policy of the paragraph lettered C, but the proper course was to hope for the best and to let things take their course [hear]. The members of that district might be sure of this, that the country Fellows would sooner see this made a most beautiful town garden, and that they would not object to the expenditure of money upon it, than to have it in its present condition. As far as he was concerned he should like to have the gardens so beautiful and so well managed that the inhabitants of that very district in which they then stood would feel themselves degraded if they were shut out of them. He was prepared to provide some portion of money for that purpose and to —

A FELLOW.—How much money? [laughter.]

MR. SHIRLEY HIBBERD, not taking the slightest notice of the query addressed to him, went on to say that it would never do for that meeting to be allowed to separate, and to allow the whole affairs of the Society to be ruled by the fortuitous arrangement of circumstances, which might, and would probably, bring about the result that next February they would find at the annual meeting of the Society the condition of the latter much worse than it was at present, and that perchance the Society had disappeared altogether in the interval [cheers and laughter]. He thought it was most decidedly necessary that they should all meet shortly and hear something like a report from the Council as to the manner in which this amended summary of privileges had been received in that very district of Kensington [cries of "no, no"]. Time was an element of the utmost importance to bring the affairs of the Society to rights. If the Society lived six months it would be a perfect miracle [laughter]. However, let them hope that the Fellows would largely increase in number through the action of what was now pretty well known amongst the Fellows as the "Amended Summary of Privileges of Fellows for the year 1876" [a laugh]. If they all met in two months from the present time, and the Council told them that the

number of Fellows of the Society had considerably increased, then indeed they might entertain every hope that their income would be augmented to the extent of £10,000 per annum [a voice "hear"]; but in the meantime they had an arrangement to make with Her Majesty's Commissioners, they had also before them the proposals for negotiations for a loan, and he was fully persuaded that under present circumstances it would be premature for the Council to complete any arrangement with Her Majesty's Commissioners, and that it would also be unwise to negotiate a loan, or if such negotiation were on foot to bring it to a completion. He confidently contended this, that the Society ought not to increase its debts to the extent of one farthing [hear, hear]. Let them see what it was best and most judicious for them to do. It would be most unjust, it would be most indecent, for them to borrow money at the present time from any one who was willing to lend it ["no" and murmurs of disapprobation]. Well, he was of that opinion, and he should therefore move a resolution to this effect:—"That the Council of the Royal Horticultural Society do report proceedings to a special general meeting to be held on Tuesday, the 25th, and that they be instructed not in the meantime to complete arrangements with Her Majesty's Commissioners, or to obtain a negotiation for a loan of money" [loud cries of "no," and some interruption]. The object he had in view was that the Council should call the members of the Society together at a certain time, so that it could be decided whether they should be allowed to proceed as they proposed to do at the present moment [no, no]. Well, but they knew the present moment was a dangerous time, and that they were placed in very extraordinary and exceptional difficulties. They had very little money in the bank, and in two months hence there might be placed before them some reasonable proposals which all of them could accept.

THE PRESIDENT.—That should be the matter of a separate resolution. We are here to-day to decide upon—to consider the Report agreed upon by the Committee and the Council with respect to the privileges of the Fellows of the Society. If there is a common expression of a wish—if there is a desire—that the propositions of the Council should be considered some months hence I shall have to say something to that hereafter. I do not know whether the adoption of the propositions of the Council of the Society has been yet proposed.

DR. PINCHES.—I have very great pleasure in moving that they be adopted [cheers].

THE PRESIDENT.—Dr. Pinches has moved the adoption of the propositions with respect to the privileges of the Fellows for the year 1876.

MR. EDGAR BOWRING, C.B., was understood to second the resolution.

MR. WILSON said he wished to say a word with respect to the concessions which had been made by the Council. There was a very great feeling in the country with respect to the fact that a very large body of horticultural Fellows had not joined the Royal Horticultural Society, but there was no doubt they would join the Society if they saw they could come into it on the former terms hanging on to their subscriptions. If they could come in for a guinea subscription as pure horticulturists they would come. If they could canvass for members of the Society when going through the country, he believed they would get a larger number of members than they could get in the immediate neighbourhood in which the gardens were situated. They were very hard-up now, it was a matter he had thought over a great deal, and he was of opinion that by getting a considerable accession of country members they might largely recover the position they had lost [hear, hear].

SIR PETER POLK remarked that discussions having taken place there in public as to their Society having broken down, a slur had been cast upon the Society in certain quarters. He had supported the Society all through its difficulties, and his reason for rising on that occasion was to state he considered this paper—the amended summary of privileges most liberal [hear, hear]. He had reason to know there were several persons who, from the knowledge that they should have to surrender their privileges, had withdrawn their names from the Society; and he knew five who, by reason of the liberal scale of privileges now offered by the Council, would become members of the Society directly [cheers]. Letters had been written to him on the subject of the Society, asking him whether it would hold together or not; but he did not give his opinion in that sort of way, but let people judge for themselves [hear, hear]. But, this he would say, that after the meeting which had taken place that day he honestly and sincerely believed that, instead of their Society breaking down, it would rise to what it was before [applause].

THE PRESIDENT wished to observe that anyone who had paid under the former regulations would have returned to them so much money as was in excess of the amount they had now to pay [hear, hear].

MR. HENRY LIGGINS said he had listened attentively to the propositions placed before the meeting, and thought they ought to be very grateful to the Council for having acted upon the sug-

gestions made to them. What they had to do was to attract Fellows back again, and act with unanimity amongst themselves. They must leave it to the Council to arrange the shows and entertainments which would be attractive to horticulturists. That, he contended, was the duty of the Council, and not of the Fellows, and he had no doubt it would be honestly and properly discharged [hear, hear]. He thought the noble lord in the chair came in a minute or two late to hear the most gratifying statement ever made in that room. It was one sufficient in its results to take the Society out of its pecuniary difficulties, and, if they had no pecuniary difficulties, whatever others they might have to contend with, they were to receive that magnificent sum of money, for which ample security would be given to the gentleman who had made this splendid offer of assistance to the Society, and who deserved their warmest and most sincere thanks [cheers]. He hoped the Council would not hesitate to receive that money, and not entail the necessity of having an adjourned meeting convened to consider the propriety of accepting the offer or not. He thought they must assume that, acting as they were on their own responsibility, they ought to be satisfied with the noble offer made them, and honourably and honestly accept the loan [hear, hear]. He hoped there would be no further adjournment of the meeting, and that the propositions placed by the Council before the meeting would be agreed to [hear, hear].

Mr. WEST begged to offer a suggestion, which was, that they should establish a band fund, and ask their friends to contribute to it.

Mr. RICHARD REDGRAVE expressed his opinion that the propositions of the Council regulating the privileges of the Fellows were far more liberal than they could have hoped for [applause].

The PRESIDENT.—I can assure you, ladies and gentlemen, that nothing but an overwhelming necessity could have prevented me being here at the commencement of the proceedings. It would, I can assure you, have been very pleasing to me to have been present at the first ebullition of unanimity which the Society has experienced for some time past [hear, hear], and which I have, I think, well-founded hope will characterise its proceedings in the future [hear, hear]. On the last occasion of our meeting in this room I made as strong an appeal as I could to the members of the Society to meet us with something like a unanimous feeling. I wished to keep before the Society the recollection of this fact, that ever since the dissensions three years ago the Society has been going down, and that the first step towards a better state of things is unanimity [applause]. Well, the Council have issued new or amended rules; but do not suppose for one moment the Council think these rules constitute a self-acting machinery. They hope these rules will bring into the Society many who are holding back from it; that they will bring to us some persons who can help us in the restoration or the raising of the necessary funds; and that must be done by a great deal of exertion on the part of the Council, and by other persons interested in the prosperity of the Society, taking the steps necessary in the case, and adopting those measures which are likely to bring about the end we all have in view—to place the Society on a sure and solid basis. I have no doubt among those measures there will be an active canvass in this district. I quite agree with the suggestion that a statement of the affairs and prospects of the Society, carefully prepared, should be issued; and that there should be personal exertions made in the district, which could be divided into sub-districts, trusting the work to gentlemen who will kindly give us their time and take the trouble to canvass those who are in a position to assist us [hear, hear]. I anticipate a resolution with respect to the funds which Mr. Bowring says Mr. Freake has so kindly and so generously promised to place at our disposal. An observation was made by a Fellow as to our giving ample security for that munificent loan. Well, really the Society can give no security; but the Royal Commissioners have offered to go security [cries of "hear"] for the payment, not of the interest, but of the capital [applause], at the end of three years, in order to put the gardens and the whole concern into what may be called a healthy and attractive condition [cheers]. We have first of all to pay our debts, then to put our conservatories, &c., into a proper condition, in order to enable people to see that they get the value of their money. Let it not be supposed all this money is to be laid out here, because we are bound to take into our most careful and serious consideration the question of what can be done for the extension and improvement of horticulture [loud cheers]. Various suggestions have been made as to how we can best gain an accession of members to the Society, and that made by Mr. Wilson is especially worthy of attention, because the machinery for making members throughout the country is a still more difficult matter than that of making them in the metropolis. We have made, we think, a considerable concession in proposing to issue non-transferable tickets at half a guinea per annum, admitting to all shows, scientific meetings, and lectures of the Society (but not to promenades nor on reserved occasions), and to the Chiswick Gardens on week days to *bond fide* gardeners recommended by two Fellows. That I

consider is a considerable concession [hear, hear]. If we see our way to enlarging our constituents without unduly affecting the receipts we expect to get we shall be very glad to do so; but, at the same time, it is not a very easy thing to draw up a distinction between these and the class of subscribers Mr. Wilson speaks of. I can assure the meeting I am delighted we have at last met harmoniously; and I believe when it is known we are acting harmoniously, not only will we get the interest of Mr. Freake's money, but the Society, which for some time past has not been spoken of with anything like respect, will recover its high position [cheers]. We have been fouling our own nests—that is the fact, and no wonder people take us at our own words [hear, hear]. If we speak injuriously and contemptuously of the Society it is no wonder that this should be the case [hear, hear]. However, we are on the verge of better things, and I am truly delighted that these rules—these regulations as to the privileges of Fellows, for which we are so indebted to Dr. Pinches—meet with your approval [applause]. We are also equally grateful to Dr. Pinches for the readiness with which he has given us valuable suggestions, and it is impossible for me to sit down without expressing my thanks to him [cheers]. I will now put it to you that these rules be accepted; but I don't know if Mr. Hibberd perseveres with his motion.

Mr. SHIRLEY HIBBERD said that after the able and exhaustive statement of the noble Chairman, and on account of the happy unanimity which prevailed in the meeting, he should gladly withdraw his motion [hear, hear].

The motion for the adoption of the "Amended Summary of Privileges of Fellows for the year 1876" was then put and carried with one dissentient, in the person of Mr. Godson, sen., who attempted to explain why he had voted against the motion, but whose remarks were inaudible.

The announcement by the President that the motion was carried was received with loud cheers.

On the motion of Dr. Pinches, seconded by acclamation, a hearty vote of thanks to the President and Council was passed, and then the meeting broke up.

NOTES ON VILLA AND SUBURBAN GARDENING.

SEED-SOWING.—Doubtless one of the most important preliminary operations before committing seeds to the ground is the proper preparation of the soil. Many seeds often fail to germinate, or if they do germinate the plants refuse to thrive, through the want of this precaution; and how vexatious it is to have to sow over and over again, and how difficult it is to keep up a proper succession of anything when this is the case. See the pains that is bestowed upon the working-up of a soil for small and delicate seeds of many choice flowers, and the relative application of heat and moisture to induce them to vegetate. Outdoors we cannot apply artificially this necessary assistance, therefore I think it is the more necessary that the soil should be well prepared. Villa gardeners would do well to study this more than they do, and as a first step pay particular attention to the drainage of the soil.

The nature of the soil and the locality, whether naturally porous or not, will govern the expense of draining; but as gardeners, whether amateur or professional, should use a good deal of water for their growing crops, the matter of draining is certainly important. Wherever draining is done, let it be so systematic that outlets be provided in proper places so that the pipes can freely empty themselves. We know what care is taken in this particular matter by gardeners for their Vine and other fruit borders in glass houses, and the advantages are well known. A well-drained soil is warmer than an undrained one, so that such a soil would sooner become warmer in spring—a great advantage for early-sown seeds.

The next thing is the proper working-up of the soil. There is a plan which many of our cottagers practise, but which cannot be recommended, and that is not to dig-up the ground till the time comes to sow the seed. It is much preferable to make the soil permeable by digging and trenching in the winter months, and then it would be found that at seed-sowing time the soil would work down finely, and be in a proper condition to receive the seeds. It sometimes happens that a stiff soil after this treatment is not easily worked-down by the rake. Soils of this nature should be improved by an addition of lighter soils at every opportunity, especially at the time of working the ground down for sowing. A little addition of lighter mould would assist the seed to vegetate.

Always choose a drying day if possible for seed-sowing, and work the soil down as finely as is called for by the size of the seed. For instance, the strong vegetating power of Peas does not require such a finely worked soil as that of Carrots or Lettuces. A seed absorbs moisture before it can germinate; and take it as a rule, the smaller the seed the finer the soil should be, in order that it may the better perform its functions through being placed in closer contact with it.

Next we come to the depth at which seeds should be sown. In this matter many are likely to fall into error. If seeds are

buried too deeply, and especially at an early season, many fail to come up, and many of those that do germinate are weakly. In support of this I will quote a very useful passage in Johnson's "Science and Practice of Gardening." It says, "The absolute necessity for the presence of oxygen is a reason why seeds will not germinate if buried beyond a certain distance from the earth's surface, and why clayey soils often fail of having a good plant—an impervious coating of clay enveloping the seed and preventing the air's access." It goes on to say that M. Burger found that "seeds of Rye buried 1 inch below the surface had their leaves above it in eight days and a half, whereas those at a depth of 6 inches had only just sprouted at the end of twenty-two days;" and further it says, "Too deep sowing inflicts another injury, though it be not at such a depth as to entirely prevent germination. It so consumes the matter of the seed in forming the useless elongation of stalk necessary to bring the leaves above the surface that all further progress in vegetation has been prevented." Enough is here quoted to warn anyone of the dangers of deep sowing, and I would rather err the other way, because when the plants are up surface soil can be conveniently added.

No doubt genial weather has much to do with the quickness at which seeds vegetate, because heat and moisture are the principal agents in influencing their progressive power. We find that in the case of such small seeds as Primulas, Cinerarias, Lobelias, and many others that these should not be buried under the soil at a much greater depth than the thickness of the seeds themselves, but then when germination has begun such a shallow covering should be kept continually moist, not so much by frequently watering as by a damp covering of moss until the seedlings are well up and have rooted into the soil sufficiently to bear a little light and air to add to their strength.—THOS. BACON.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

We like to have all the nailing done early; and as our wall trees receive nearly all the pruning and training they require during the late summer months, there is but little to do in the winter except to look over the trees, to re-arrange the young wood, and replace any fastenings that have decayed. Where there is a very large extent of walls covered with fruit trees, and not more than sufficient assistance to do the work, it is not easy to have all the wall-pruning and nailing done in good time, the more so when the winter has been severe; for even if men are sent to such work they cannot do it with the thermometer below the freezing point. The Peach wall is generally left to the last, and to make satisfactory work of this it is best to undo the trees entirely from the walls.

It may not be out of place to make a few remarks on the Peach as a wall tree. Nearly all stone fruits require a deep clayey soil to grow them to perfection, and to grow the Peach wall the soil must be deep good clayey loam, not stiff adhesive clay. If the soil contains too much clay, the best corrective to it is good leaf mould as free as possible from decayed wood; if the ground is not naturally dry it must be drained. On the other hand, light sandy soil may be improved by adding stiff clay. First, as to young trees. Of course they were selected and planted in the position intended for them in November, and the ground will have sunk down enough by this time to allow of the trees being pruned and nailed. The trees if they were selected from a good nursery will have three, five, or seven shoots. Now some growers would cut off two-thirds from the length of these growths, but if the trees were planted at the right time, and had plenty of fibrous roots, not more than one-third of the length should be cut off close. But no rule can be laid down, as much will depend upon the health and vigour of the trees. The two lower shoots should be brought down to an almost horizontal position, then the centre growth must be trained vertically, and the other growths equidistant between them. The same system holds good with the large bearing trees; the main branches should be nailed in first, and the young bearing wood must be judiciously placed between them.

If it is necessary to cut-back any of the young wood it must be cut at a triple bud; the middle bud of the three is usually a leaf bud. Very few of the smaller growths are furnished with leaf buds except the point of the shoot, which is always one. The round buds are all flower buds, and to cut at one of them is to destroy the growth, as no shoot will be produced. If the protecting material is not in good condition it must be seen to at once. Indeed, as soon as the trees are nailed this may be fixed if the canvas can be rolled up under the projecting coping, where it is protected from rain.

Apple and Pear trees intended to be regrafted should be headed-down at once if this has not been done, and the grafts may be put on as soon as it is seen that the sap is in motion. There is nothing now requiring to be done amongst the pyramid and other trees in the borders. The ground between them has been manured and dug.

VINES.

There is now plenty of work in the early houses, training and stopping the laterals which are now pushing very rapidly. Some varieties of Grapes do better trained on what is usually termed the short-spur system than others; the free-bearing varieties, such as Black Hamburgh, Muscat of Alexandria, Lady Downe's, Royal Vineyard, Mrs. Pince's Black Muscat, and a few others may be spurred pretty closely back year after year, and still continue to produce abundant crops. Other sorts must either have the spurs left longer or young wood must be trained-up from the base of the Vines annually. Canon Hall Muscat, Golden Champion, Gros Guillaume, Buckland Sweetwater, and White Frontignan must be classed amongst those that succeed best with frequent renewals of the young wood. The Canon Hall Muscat will not show bunches at all from closely-spurred laterals on an old rod. We train the lateral growths all about the same angle, say 45°; some persons train the young wood in a horizontal direction from the rod, but this is not usual.

Our Vines are now in flower, so that a higher temperature is being kept up with less moisture in the atmosphere. The Muscat house is about 75° at night, and the Hamburgh house 70° in very cold weather. If the glass registers 5° less than this we do not mind it. The bunches are gently shaken twice a-day, about 10 A.M. and 1 P.M. Late houses are all ready to start, but we shall not hurry them at present, as the houses are so useful for bedding plants until they can be placed under canvas out of doors.

Red spider may be expected very soon to appear in the earliest houses. A correspondent, "J.C.," makes some remarks on destroying it last week. His plan is reasonable and well worth a trial, but he ought not to say that "it answers no good purpose to paint the pipes with sulphur, but the reverse." Now we have repeatedly painted the hot-water pipes with sulphur and destroyed the spider. I have had so much experience in this that I can tell whether the fumes arising from the pipes is strong enough by remaining in the house for a few seconds, and when the fumes are strong enough the fire is checked at once. Mr. Rivers in one of his books recommended slaking lime in the house and throwing a handful of sulphur upon it. This we tried once, but the lime was not strong enough. Better lime was obtained fresh from the kiln, and the same process was repeated in a house of splendid Grapes just colouring, with the result that almost every leaf was killed in the house, and the crop lost for that season. That was my first and last attempt with lime. We only used a 9 or 10-inch potful of lime, but it caused the sulphur to burst into a flame. Of course, the pot was hurried-out immediately the flame was seen.

PEACH HOUSE.

When the trees in the early house are in flower the atmosphere ought not to be very moist—only sufficient to counteract the drying heat of the pipes. When the fruit is set the trees should be well syringed to wash off decaying petals, and the syringing to be continued daily. The Peach is more liable to the attacks of red spider even than Vines, but to syringe the Vines would be to sadly mar the appearance of the fruit, whereas the Peach is not injured in the least by the free use of the syringe or garden engine. Of course the water must be a little warm. All water used for syringing ought to be. The water-pots ought to be filled with water and placed upon the hot-water pipes, the water will thus be slightly warmer than the atmosphere of the house.

Continue to disbud, not rubbing-off all the shoots that will ultimately be removed; to do so may check the trees. One growth at the base and one as a leader to each shoot is the proper number to leave on. When the trees are in good health the fruit may be severely thinned very soon after it is set. About double the quantity that will ultimately be allowed to ripen should be left on until nearly the stoning period. If it is all right after stoning begins very few fruits will drop. We have thinned our fruit on the pot trees to the required number before stoning, and have lost but very few from dropping off. The inside borders must be well supplied with water. When in full growth the Peach requires a large supply, and dryness at the roots is very injurious.

CUCUMBER HOUSE.

The instructions given in previous numbers are so much like what is being done in this department that little additional need be said. We keep the night temperature up to 70° now, rising to 85° or 90° in sunshine. Plenty of heat and moisture in the atmosphere suits Cucumbers, but they may be overdone with moisture. In our small house are two 9-foot lengths of water troughs, and when these were both kept filled with steaming water the leaves became flabby and thin in texture. When one of the troughs was emptied an improvement was speedily apparent in the general health of the Cucumber plants. The importance of sufficient ventilation was found out by accident. The young man in charge used to open the top ventilators only, until it was observed that the plants were gradually becoming weakly, when we tried opening the front sashes just a little, admitting less air at the top; this soon told upon the plants for

the better. The modern system of glazing with large panes fitted closely almost entirely excludes air, except what is admitted by the ventilators.

GREENHOUSE AND CONSERVATORY.

The cold winds and unfavourable weather at this season should urge us to do all we can to make the above structures attractive. We always contrive to have the best display from now until the end of June; by that time plenty of flowers can be obtained out of doors. It is also necessary to be careful how the ventilators are opened. If the house is constructed with the ventilators to open on either side it is very easy to air the house on that side opposite to which the wind is blowing, and if the wind is not blowing quite a gale the side next the wind should be opened a little.

We are now busy with the Chrysanthemums. Specimen plants are being trained, and as they require it are repotted. The specimens are grown for exhibition, and it is necessary that they be started early, for although size does not go before quality, size and quality combined are the most desirable objects to aim at. The growing shoots are carefully tied down as they advance in growth. The plants intended for out blooms are now in a cool frame, to which air is freely admitted. It is necessary to fumigate them to prevent green fly from spreading. This pest must be destroyed at once.—J. DOUGLAS.

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

LIVERPOOL (Spring Show). March 5th. Mr. R. Wilson Ker, 6, Bassett Street, Church Street, Hon. Sec.

LANES (Spring Show). March 15th and 16th. Mr. G. Forbes, 106, Hyde Park Road, Sec.

BIRMINGHAM (Spring Show). March 22nd and 23rd. Mr. G. Wesley, Holm Wood, Westbury-upon-Trym, Hon. Sec.

GLASGOW. March 25th, May 10th, and September 12th and 13th. Mr. F. Glib, Dughall, 167, Canning Street, Sec.

ROYAL CALLEDONIAN HORTICULTURAL SOCIETY. Shows April 5th, July 5th, and September 12th.

WHITBY AQUARIUM. April 19th and 19th, May 10th and 11th, May 30th and 31st, July 5th and 6th.

TIVERTON. May 24th and 25th. Messrs. A. Payne and J. Mills, Hon. Secs.

MARCHESTER (Grand National). June 2nd to 9th. Mr. Bruce Findlay, Royal Botanic Garden, Sec.

SOUTHAMPTON. June 5th, and August the 5th and 7th. Mr. C. S. Fudge, 40, York Street, Sec.

MADISON (Hoses). June 21st. Mr. Hubert Bamsted, Rocketow, Maidstone, Sec.

SPALDING. June 21st and 22nd. Mr. G. Kingston, Sec.

BRIGGATE (Hoses). June 24th. Mr. J. Payne, Treasurer.

BIRMINGHAM. June 25th. Mr. A. Chancelor, Hon. Sec.

FLORIN (Hoses). June 26th. Mr. A. E. Baily, Hon. Sec.

SOVEREIGN. July 5th, 6th, 7th, and 8th. Mr. E. Martin, Sec.

HELMERSBURY (Hoses). July 12th and 13th. Mr. J. Mitchell, Sec.

WINDSOR. July 15th and 18th. Mr. P. Appleby, 6, Linden Cottages Hon. Sec.

BRIGHOUSE. July 20th. Messrs. C. Jessop & E. Bawley, Hon. Secs.

HEWORTH (Horticultural). August 2nd. Mr. E. Feltow, Hon. Sec.

CLAY CROSS. August 15th. Mr. J. Stoddard, Clay Cross, near Chesterfield, Sec.

PENSWORTH. August 16th and 17th. Mr. W. Troughton, Hon. Sec.

SHREWSBURY. August 16th and 17th. Admits & Neanton, Hon. Secs.

SEATON BURK. August 23th. Mr. R. Richardson and Mr. W. Elliot, Secs.

DUNDEE (International). September 7th, 8th, and 9th. Mr. W. R. McKelvie, 26, Euclid Crescent, Sec.

TRADE CATALOGUES RECEIVED.

George Yates, 29, Little Underbank, Southport.—*Descriptive Catalogue of Select Vegetable and Flower Seeds.*

James Backhouse & Son, York.—*Supplementary List of New and Rare Alpine Plants.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*Cultivator*).—The "Fern Book" is preparing for publication.

GARDEN PLANS (S. G. B.).—We know of no work teaching the mere elements of such drawing. London's edition of Repton's "Landscape Gardening" is full of information relative to drawing and designing gardens.

WRITH OYSTER (Herefordian).—It is not uncommon. We cannot answer your other query.

ADOURA BERRIES (*Cabochemen*).—An answer in our last number contains the information you ask for.

PRUNING FRUIT TREES (A. C.).—Mr. Rivers has published "The Miniature Fruit Garden," which contains directions for some kinds of pruning. Its price is 3s.

FUNGUS ON BROOK TREES (H. L.).—A creamy mixture of lime in a brine of common salt applied with a brush will destroy it. Some soot added to the mixture prevents the whiteness being an objection.

THUJA AURUM INJURED BY DOGS (F. M. S.).—Dogs, not cats, have caused the injury, and beyond what you have done to prevent a recurrence of the evil you can add nothing; congenial weather will do the rest. We could not without seeing the shrubs tell whether they will recover. All the parts affected as you describe will die, and probably the plants if the stems are injured.

HEELING BROCCOLI (*Idem*).—It is done to protect the plants, or rather their stems, from destruction by severe weather, the soil being taken out at the back of the plant in a sort of trench, into which is laid the stem of the plant with its head inclining northwards, the whole of the stem up to the neck being covered with soil, and the roots which will be exposed by the operation being also covered with soil, previous to which a good watering is given if the weather be dry. Layering checks growth, and enables the plants to withstand severe weather better than those not operated on. It should be done the early part of November.

PRUNING RECENTLY-PLANTED VINES (A Young Gardener).—The Vines with canes 6 feet long should be cut back to the bottom of the rafter or where you wish to originate side shoots or spurs; but as the time is past for pruning without a certainty of bleeding we should depress the points of the canes from whence you wish shoots originated, and rub off the eyes from which you do not require shoots, and should not leave more than three shoots—two side shoots and a leader, removing all others. Leave the fruiting canes in the pots.

PRUNING PEACH TREES (*Idem*).—Cut back the strong shoots half their length, and the moderately strong about one-third, and the others in proportion to their strength. The trees will be weakened by removal, and unless pruned they will make a very poor growth this season.

GRAFTING PEARS (F. J.).—Better not insert more than one or two grafts in a stock, and as near a foot from the ground as practicable. A dozen to eighteen grafts on each tree would in a measure fail, and if all grew the upper grafts would be the most vigorous, appropriating the sap. For a pyramid you must begin at the bottom and work upward, forming the tree in the second as in the first instance.

MANAGEMENT OF BEDDING PLANTS (*Idem*).—A fortnight is too short a time for keeping bedding plants in bottom heat after potting. They should be kept in the heat until well rooted, the roots working freely in the fresh soil; the plants should then be hardened off, placed in the cold frame, and kept rather close for a time.

PRUNING ROSES ON MANETTI STOCKS (*Idem*).—Cut away all the old and weak shoots, and shorten the others to four or six eyes according to their strength; but at the distance your plants are apart we should have at least twice the number of shoots you name, having some of the weaker wood pruned to two or three eyes. Now is a proper time to prune them.

TRANSPLANTING HOLLIES FROM WOODS (A Novice).—The best time to transplant Hollies from such a position as you describe is from the middle of April to the first week in May, according as the season is forward or late, they being best moved when commencing growth. We do not think you will have much success, as the roots are often long and fibrous near the stem, and being in the shade they do not, when moved to the open, do nearly so well as those grown in full exposure previously. We should now take out a trench all around the trees 3 feet from the stem, cutting off all roots in the trench, and going down as deep as the roots extend. We should then fill in the trench and leave them until April twelvemonths, when you may be able, from fibres being formed near the stem, to move with a ball, at least doubling the hope of successful removal.

PROPAGATING VARIEGATED EUCONYMUS (A. J.).—Take cuttings of the young shoots after they become rather firm in July or August, and insert in sandy soil in a warm border, covering with a handglass, and shading from sun, or insert in pans or pots, and place in a cold frame kept close and shaded. Young shoots strike sooner in gentle heat.

PRUNING CLEMATIS JACKMANI (*Idem*).—Cut away the old and bare shoots, and leave those which have firm ripe wood with prominent eyes at about a foot distance apart, removing only their points down to good eyes. If you want shoots at the base you must cut back some of the shoots so as to give others at the places required.

TRIMMING NEWLY-PLANTED HORNBAM HEDGE (*Sussex*).—We should not trim it this year, but allow it to become established, and before growth takes place next year trim in rather closely.

EUCALYPTUS GLOBULUS (*Idem*).—It would succeed against a wall if the ground were well drained so as to insure dryness, but except in very warm sheltered situations it is not hardy. It is sufficient if the soil be damp, a wet soil only making it more susceptible of injury from cold.

PLANTING HARDY AQUATICS (H. H. F.).—The best time is during March and up to the beginning of May, but it may be practised at almost any season, but preferably in the spring.

NITRATE OF SODA FOR VINES (C. B.).—We have no information, but we should not object to applying 1 lb. dissolved in ten gallons of water. Try it to one vine, and inform us of the effect.

HANDLENITS (*Cheshire Amateur*).—We cannot give the information. Write to Mr. Gilbert.

SETTING CUCUMBER BLOSSOMS (A Beginner).—Apply a stamen of a male flower to the pistil of each female flower. "The Garden Manual" will suit you. You can have it free by post if you enclose twenty postage stamps with your address.

ANNUALS FOR ROSE HOUSE (B. E.).—For your unheated Rose house *Tropaeolum* and *Convolvulus* would be suitable for covering space quickly and effectively. *Tropaeolum canariense*, *T. Lobbianum*, and other varieties are rapid-growing free-flowering annuals. *Convolvulus major*, *Ipomoea limbatia* elegantissima, and *I. Quamoclit* may be grown, sowing the seed in April where the plants are intended to flower, except the latter, which should be sown in heat and the seedlings transplanted, as also should *Lophospermum secundum* and ornamental *Gerardia* in variety.

ANNUALS FOR BEDDING (*Sussex*).—*Convolvulus tricolor splendens* forms a fine blue bed, and is lasting; *Saponaria calabree* makes a splendid pink bed of long continuance; *Nasturtium King of Tom Thumbs* affords scarlet, and

Tagetes signata pumila yellow. The three first named may be sown in the beds early in March in drills, covering the seeds with their own thickness of fine soil. *Tagetes* with Stocks, Asters, *Phlox Drummondii*, *Petunias*, and Indian Pinks are better raised in gentle heat, transplanting the seedlings in rich light soil, and at no period suffering them to become drawn by sowing too thickly or by a too long continuance in heat. Unless you have means to grow the plants on gently and steadily it would be preferable to defer sowing the seed until the last days of April or the first days of May, sowing them in rich light soil on a warm south border in the open air. All or any of the above will be useful supplements to your ordinary bedding plants.

PRUNING MARSHAL NIEL ROSE (*Wills*).—Do not cut away more than the unripened points of the shoots, leaving the shoots of 8 or 10 feet their full length if the wood is well ripened. It is a Tea-scented kind, and therefore a continuous bloomer.

CULTURE OF HEDYCHUM GARDNERIANUM (*H. B.*).—Repot when it begins to grow, removing the loose soil, and give a moderate shift. Water moderately for a time, but when in free growth water freely, maintaining a moist atmosphere, affording a light position. When the growth is complete admit more air, keeping drier and fully exposed to light. In winter keep rather dry and cool, but safe from frost, cutting away the old stems when yellow. Sandy fibrous loam and peat in equal parts, with a fourth each of leaf soil and old cow dung, with a free admixture of sand, is a suitable compost.

DIVIDING CHRYSANTHEMUMS (*Idem*).—Take off the rooted offsets and insert them three in a 4-inch pot around the sides, and place in a cold frame until established, and when the pots are filled with roots shift into 7-inch pots, stopping when 6 inches high; or divide the plants, and retaining three to five of the strongest shoots to each division, and pot each singly, trimming-in the roots so as to be potted in 5-inch pots.

SOWING WALNUTS (*B. S.*).—It is best to sow them in the open ground in the autumn, when they will come up in the spring. They may still be sown, planting the nuts about 2 inches in the ground. The plants ought to be trained to single stems before allowing them to branch. The height of the stems may vary from 2 to 30 feet long. Walnut trunks are very valuable.

TRAINING VINES (*L. H.*).—We approve of fixing the wires in a horizontal position, and the lateral growths may be trained horizontally, but we prefer training them at an angle of 45° to the rod. It is probably ordinary mould that is around the buds; it would not be mildest after you had coated the rods with Glabur compound. We hardly know how to answer your next question; it is, "Are coals injurious to plants?" Burning coals would be if the smoke and plants were confined together in a house. A few pieces of coal strewed on the ground would not be injurious.

PLANTS FOR BEDDING (*H. B. C.*).—*Tagetes signata* pumila, *Pedilla nankinensis*, *Centaurea candidissima*, *Ageratum*, *Saponaria calabrica*, and *Mæconbryanthemum tricolor* could all be used with the different sections of the bedding *Pelargoniums*. You merely say "*Geraniums*," which is not a sufficiently distinctive term to use when you write for the information you desire.

NORTH LAWN FLOWERS (*Amateur*).—The *Lobelia* and *Alternanthera* would, in a warm shaded place, retain their beauty longer than if more exposed to the sun.

GROWING GARLIC, &c. (*J. B., South Hackney*).—Send us five postage stamps and your full address and order "Kitchen Gardening for the Many." It contains all you ask for and much more.

SLOW-COMBUSTION BOILER (*A. B. C.*).—We have no experience of this boiler. Write to the maker and tell him your difficulties. Other answers next week.

INSECTS DESTROYING IRIS RETICULATA (*G. S.*).—The beetle "having devoured 1s. 6d. in the shape of a plant" is the common *Carabus hortensis*. The species of the genus *Carabus* are eminently insectivorous, their prey consisting of larvae, herbivorous beetles, and other insects, one of the species, *C. auratus*, being known in France under the common name of "Le Jardinier," or the Gardener, from the services it renders in gardens by destroying numbers of female cockchafers when in the act of depositing their eggs—hence we doubt the statement of "G. S." that *C. hortensis* had devoured his Iris, supposing that the mischief had been done by some other insect. Can "G. S." supply evidence to prove *C. hortensis* to have been the real culprit?—*I. O. W.*

NAMES OF FRUITS (*O. Y., Mortlake*).—Shepherd's Newington. (*W. G.*).—1, Tower of Giammi; 2, Baldwin. (*G. C.*).—1, Ronselet De Jonghe; No. 2 is Marsh Bergamot, and not Comte de Lamy. (*Connaught Subscriber*).—1, Cornish Gilliflower; 2, Not known; 3, Loan's Pearmain; 4, Dumelow's Seedling.

NAMES OF PLANTS (*Subscriber, Co. Cork*).—*Berberis japonica*. (*Mrs. Huddleston*).—The large leaf, *Cyclamen europæum*; the round-leaved *Cyclamen coum*; the blue flower, *Omphalodes verna*. (*F. H. F.*).—Yours are florists' flowers, of which we cannot name varieties, they are too much alike.

POULTRY, BEE, AND PIGEON CHRONICLE.

POULTRY FARMING.

"A. B." writes to us for information, but as his locality is not named it makes it more difficult to advise. We confess we do not believe in poultry rearing and in keeping hens for eggs for purely domestic purposes. We do not mean that a few fowls kept about a house do not answer, for they do, and very often well, and there are not many country houses without them; but to go in for a large number because a few pay, on the principle that because ten hens lay 1200 eggs in a year that twenty hens must lay 2400, is where the mistake is so often made, and which brings such woeful disappointment on the breeder. No; we do not believe in poultry farming on the scale which so many think would pay—namely, of hiring so many perches of land, and erecting houses, stocking the runs, and then waiting for profits. We fear patience has to come into use greatly in such a case; for putting aside a per-centage for interest on money expended, paying for food, rent, labour, and such like must leave only a tiny balance

on the credit side, and then only when the proprietor does not leave the work to attendants but does the greater part himself, and is always at hand to superintend. The profits made by the Sussex and other county cottagers are of course great; but then they work on a small scale, and are so able to feed the birds and attend to them much more than if they had larger numbers. When their chickens are ready the higglers come round and collect them, and then other broods are brought up to take their places; but it is only because of the small size of their undertakings that they may make at times forty per cent. or even more, as no doubt they sometimes do; but once they were to get overstocked their game would be done.

We can never recommend anyone to invest money on laying out yards for poultry for table purposes. The expense would be great and the results unsatisfactory. It has been tried and proved by many to be a failure, and "The Poultry Book" tells us, too, that these establishments always collapse. They have had a very fair trial and the food has been various and good, but never has any real success been recorded. Companies, too, have been started, but the prospectus has invariably been drawn up upon some foolish and ridiculous basis, that it is needless to say they did not answer or would not have done had they struggled into life.

The largest scale of poultry farming for domestic purposes that can ever be attempted with success are the poultry yards connected with large farms. In such a case at one homestead it would be impossible to manage more than two runs where the birds could have perfect freedom and unlimited runs. Were we going to attempt the cultivation of poultry for eggs and chickens we should try and rent the farmyard of some large farm for the run of the birds alone. We believe this can be done and is actually being done. The food collected by the birds themselves in their wanderings over yards among the loose manure, around the cornstacks, in the fields, and in such places is immense, and would go a long way towards keeping them fed, and at the same time keep them in the most robust health. Ducks, too, might be added with success. Turkeys we would have nothing to do with. In no way depreciating them, but they are apt to be delicate and get in the way of growing chickens. Such a farm we would stock with Black Hamburgs for laying, and Brahma-Dorkings for table and sitting purposes. No doubt others can recommend breeds which with them have been very useful and prolific, in which case people would use their own discretion in their choice. We have found Black Hamburgs wonderful layers of good-sized eggs when kept in a farmyard, and we know the meat of Brahma-Dorkings is juicy and good. A good-sized farmyard where the cornstacks and foddering yards are numerous should take from fifty to a hundred hens. We would never go beyond that number. Supposing the birds could not be divided and all had to run together we would substitute Houdans for Black Hamburgs, as the former are good layers and they make a good table cross, otherwise the Hamburg eggs would be used for sitting, perhaps, which would hardly produce pretty table chickens.

For cooks we should have a large-bodied Brahma with not heavily-feathered legs, or the first cross between a Coloured Dorking and a Brahma. Three or four or more would live peacefully together if properly managed, and each would most likely take a certain number of ladies under his chaperonage. By always letting the cooks be of different ages and hatched one under the other we have generally noticed that the younger are afraid of the older, and run from them.

Supposing, of course, it would be practicable to hire some farm homestead for the fowls only, we think a fair price might safely be paid for rent, as with personal supervision the results should be good; but great care would have to be taken in looking-up the eggs regularly, for the hens would be sure to lay in mangers, and cribs, and out-of-the-way places where two-legged foxes would always be ready to lay their hands on any stray eggs.

We hope we have not damped "A. B.'s" ardour as a rising poultry farmer in embryo, but we cannot recommend anyone to enclose wire runs for keeping birds for eggs and rearing for table; for as we said, many good and practical people have tried it and found it not to pay.—*W.*

PROFITABLE POULTRY-KEEPING.

In our issue on February 10th Mr. Webb stated his experience under the above title. A correspondent asked for more particulars, and in reply Mr. Webb has obliged us by sending the following details:—

On February 1st, 1875, I began with ten hens and one cock. On February 1st, 1876, I had in stock forty-three fowls. I killed during the twelve months thirty. The average cost of food, &c., has been £1 per month. Indian corn is 16s. 6d. to 18s. 6d. per bag. Tyler's patent poultry meal, 18s. per hundredweight. Price of eggs in January, seven to nine for 1s.; in February, ten for 1s. Fowls fetch 4s. to 4s. 6d. each. My success would have been greater had I not set four hens with Duck's eggs, and reared only seven, which I killed and reckoned above as fowls

Thus I lost much time with four out of ten hens. This month (February) I am certain of four hundred eggs, and I have two hatches of chickens.

DUBBING OF ALL GAME COCKS.

I AM very glad to find that my few words on this subject have called forth two somewhat long letters. If a pond stagnant and foul remains undisturbed it may be doing abundant mischief to those near. But it is not so very offensive. It is an old pond, it is mantled with green, and has a decent look, and people tolerate, or forget, or rather like it; but get it well stirred up, let its hidden nastiness come to the surface, let its vileness taint the air, then people say "Clean it out, clean it out," or "Do away with it." Dubbing is the pond, the press stirs it up, attention is directed to it, and truly thankful am I that the subject has been caught-up, and I hope it will be more and more written against and talked against until the dubbing of all Game fowls for ever ceases. I only mentioned Game Bantams, as they are much liked by ladies, and I know that more ladies would keep them was not dubbing required as a condition of showing with a chance of success. I heartily approve all that "SURREY PARSON" states. He in attacking the Crystal Palace Show simply goes further on the right road than I ventured to do. He would carry by assault, I only attacked by skirmishing.

Another and very different letter appears printed immediately beneath "SURREY PARSON'S," and has the name of "FRIZ" at the end of it. This letter I do not approve. "FRIZ" says I insinuate that the level of Game Bantams is about equal to Black Bantams. I do not think them on the same level at all. Game Bantams are below Black Bantams, just as White Pouters are below the Pied varieties, for this simple reason—they were only recently made. We all remember the time when no such a bird as a Game Bantam existed, whereas Black Bantams, White, and Nankin were in England in the last century. From the last-named Game Bantams were principally made, and I possessed some Duckwings which threw pure Nankins. Then next as to Black Bantams being often "Black Game Bantams with rose, comb, and ears." I, an old Black Bantam breeder, say that this is incorrect. New breeds are made from what before existed, but the reverse is of course not possible. Next about dubbing. I have been familiar with Game fowls from childhood, being the son of one who always kept them.

"FRIZ" seems to object only to cock-fighting because it leads or necessitates gambling. As to that, men will gamble, and have gambled about the race of two raindrops down a window-pane. Gambling is detestable, but cock-fighting is to be specially stamped-out because of its cruelty. "FRIZ" thinks that there is as great cruelty in coursing a hare. The cases are not parallel, and the logic of "FRIZ" is at fault. Hares are killed for food, just as oxen and sheep are. Killing them by the aid of dogs is the oldest kind of hunting. They were so killed before guns or even bows and arrows were dreamed of. But whoever fought cocks for to supply man with food? Then "FRIZ" makes much of the fighting being in the birds, that they want no urging, &c. But who made the Game cock? Who? Why man, not God. When I see the prize bulldogs lying on their benches at a show, with lower jaw so far protruding, so that in the poor dog's case his very tongue cannot be hidden in his mouth, the upper jaw being too short—when I see this villainous aspect of the poor dogs I say to myself, "Man's wickedness made you; not Him who made the shepherd dog for man's use, and the dog in general as man's friend." Man has bred and bred together certain specimens with furious nature and deformed aspect, until by selection he has produced a beast unnaturally savage and unnaturally formed.

So too exactly of the Game cock. For generations, possibly for hundreds of years, the most savage have been selected and bred from until the bird ceases to do what he would naturally do—fight a bit until beaten, and then run away. Man's wickedness made the bulldog and the Game cock, and the fighting to death is in him because put in him by breeding and kept up by stimulating food.

"FRIZ" wonders what I mean by saying, "Once let Game cocks be dubbed and cock-fighting is for ever at an end;" and imagining, I suppose, that I am "a muf" as well as a clergyman, proceeds to say, "If 'WILTSHIRE RECTOR' thinks that by not dubbing Game fowls he will prevent their fighting, he will find he has made a mistake. This is worse than the bread-and-milk theory." It really seems absurd that I should have to explain my words, as everyone save "FRIZ" would know what I meant.

1st. Why have Game cocks been always dubbed? To enhance their beauty? By no means. A cocker had no eye for artistic beauty; he was too low class for that. See how he trims the poor bird, and the fright he makes of him—tail out to a triangle, all the beautiful arch of the feathers gone, hackle cut, saddle ditto. The creature who did and does this (and I have not been in and out of the poultry world for fourteen years without knowing that certain Game breeders now fight their birds on the sly),

had and has no eye to beauty. Was it, then, from kindness the poor bird's wattle and comb were cut off? By no means. The cocker knows no such feeling. Why was it done? Why simply to prolong the battle, for if the cocks were undubbed the most active bird would seize the other by the comb, hold him, and in would go the steel spurs, and the battle be over in a moment. Dubbing was to prolong the sport, and if it be done away no cock-fighting to satisfy the cocker could be had.

Let it be clearly understood that apologies for dubbing are in reality apologies for cock-fighting. Stamp out the one you stamp out the other.

I earnestly hope that if "FRIZ" ever again ventures into print he will have a worthier subject. In conclusion, I call upon all readers of "our Journal" to aid me in putting down this cruel dubbing, in itself cruel and leading to greater cruelty. The Editors of this Journal aim, I know, to help to do away with every iniquity or cheating connected with poultry, and I object to "carving" and "stitching" as well as dubbing; both are cruel, but, unlike dubbing, they do not lead to fighting.—WILTSHIRE RECTOR.

MR. WILLIAM DRING.

THE readers of the poultry portion of the Journal, and the lovers of poultry in general, will be grieved to hear of the death of one who has for many years occupied a foremost place at all the great exhibitions, and who has done as much as any man to improve the breed, in which he was especially interested—the Crève-Coeurs and Houdans—Mr. Wm. Dring of Faversham. As I have been interested in these same breeds, it was my lot to be brought into frequent contact with him, especially as we were comparatively near neighbours. He was most thoroughly straightforward and upright in all his dealings, ever ready to acknowledge the excellence of the exhibits of his competitors, having no secrets, and always ready to communicate information to others. He was (as all who ever met him knew), most enthusiastic in his pursuit, and with by no means great appliances managed to obtain a prominent place as an exhibitor and breeder. To the poultry shows of his own county he will be a very great loss, and all who had the pleasure of his acquaintance will feel that they will lose one of the pleasantest features in not being able to shake him by the hand and hear his trenchant and sound remarks on the character of the show. He was much respected and valued in the extensive business in which he was employed, for his love for his hobby in no way interfered with the diligent fulfilment of his duties. Would that all who are engaged in the "fancy" had the same upright and honest method of conducting business that our friend had, we should not then hear of so many complaints.—D., Deal.

[We have another tribute to the memory of Mr. Dring, but it is needless to add more than that he died on the 26th of February.]

ALEXANDRA PIGEON SHOW.

THIS was held at Idle on February 26th and 28th, when the following awards were made by the Judge:—

PIGEONS.—*Antwerps, Long-faced.*—Cock.—1, H. Jennings, Allerton. 2 and 3, C. Hopwood. *do.* B. Rawnsley, Goldstock, Bingley (2). *Long or Medium-faced.*—Hen.—1 and 2, C. Hopwood. 3, H. Jennings. *do.* J. Cockitt, Great Horton. *Short-faced.*—Cock.—1, Miss E. H. Entwistle, Wyke. *do.* J. S. Collier, Rochdale; T. Bottomley, Great Horton; Miss E. H. Entwistle. *Hen.*—1 and 2, J. S. Collier. 3, B. Rawnsley. *Any variety.*—Young.—1, B. Rawnsley. 2, H. Jennings. 3, G. Collins, Great Horton. *do.* A. Brook, Horton; E. M. Pearson, Liverpool. *LIVERPOOL BIRD FOR FLYING PRIZE.*—1, B. Rawnsley. 2, H. Jennings. 3, E. Marshall, Yeadon. *do.* J. Holden, Wibsey; J. Lister, Keighley; T. H. Stretch, Ormskirk. *ENGLISH OWL.*—Cock or Hen.—1, J. Thresh, Bradford. 2, W. Ward, Otley. 3, F. Eastwood, Littleborough. *do.* J. Brown, Stoneclough; G. Holton, Dracoon. *do.* Cock or Hen.—1, H. Jennings. 2, S. Wade, 3, W. Ward, Otley. *do.* B. Rawnsley. *TOURTELLIN.*—Cock or Hen.—1 and 2, B. Rawnsley. 3, J. W. Smith, York. *JACOBIN.*—Cock or Hen.—1, 2 and 3, T. Holt, Bradford. *LONG-FACED TUMBLERS.*—1, J. Brown, Stoneclough. 2, B. Rawnsley. 3, J. Carall, York. *do.* J. B. Winspear, Scarborough. *ANY OTHER VARIETY.*—1, T. H. Stretch. 2, B. Rawnsley. 3, G. Thickett, Rochdale. *do.* J. Cockitt; B. Rawnsley. *SELLING CLASS.*—1, B. Rawnsley. 2, T. Holt. 3, H. Jennings. *do.* B. Rawnsley; A. Smith.

JUDGE.—Mr. W. Lund, Shipley.

A GOOD EXAMPLE.—We are informed that all prizes awarded at the Kendal Show were paid on the 22nd of February, that is within ten days after it closed.

APPRECIATION OF LARGE HIVES.

"THAT fellow does not know much about bee-keeping in this cold country, otherwise he would use smaller hives," said some of the Lancashire bee-keepers when they first saw my hives placed amongst theirs on the Cheshire moors. Ten years ago a great writer on bees stated in a respectable gardening periodical that "Mr. Pettigrew's large hives are a delusion and a snare." A great change has taken place in the opinions of enlightened apirians. The logic of facts has ploughed up the fallow ground and destroyed the weeds of prejudice. The most enlightened

and active men of the bar-frame school have been won over to the side of capacious hives for their bees. It appears to me that they will require no more stimulus from our school. They will speedily find that the adoption and use of large hives will put them on the high road to great success in bee-keeping, or in other words to large harvests of honey.

The remarks I ventured to make lately on the proposal to have a standard bar-frame hive have been well read and understood. From a private source I have learned that Mr. Abbott's bar-frames are now 17 inches square by 11 inches deep inside measure, containing 8179 cubic inches of space. I am pleased to know this, for Mr. Abbott holds an influential position among apirians, and his hives and example will be extensively copied. Hives of this size will hold a great many bees and do much work. The size of hives is of greater importance than their shape. Every bee-farmer, on finding that his bees have power and scope to yield large harvests of honey, directs his attention to the most profitable mode of management and the best shape of hives for that mode. The shape of Mr. Abbott's hive is suitable for swarming and supering, but very unsuitable for furnishing the breakfast table with bars of pure virgin honeycomb. From hives of 3000 cubic inches of space much pure honeycomb may be obtained, far more than from smaller hives; but I mean whole bars of honeycomb would be more abundantly obtained from the hives if they were considerably longer than they are broad, but of this more will be said at another time. Meanwhile we would like to encourage all active apirians, whether they keep bees for profit or pleasure, to have hives about the size of Mr. Abbott's, and of any shape they like. In the remarks I have referred to on "a standard bar-frame," and suggested that the size should be 3000 inches at least, but I scratched out the words "at least," lest some should be frightened from going in the right direction. But seeing that the bar-frame school are now in the van as to size of hives, I shall take care not to scratch out these words again.

It is very gratifying to know that the science and art of bee-keeping are making very rapid strides. Testimonies and evidences of this come from all quarters. Application for stocks of bees are coming here thick and fast. Three or four have come within the last few days, and one of these for twenty hives. I mention this as a hopeful sign of the increasing interest that is taken in bee-keeping, and also with a view to let it be known that at present I have no stocks on sale. All I had to sell were disposed of last autumn; indeed, the stocks were reduced in number to two dozen. I had resolved to reduce them to ten hives and keep these simply for experiments, but I have changed my mind, and will again increase the stocks both in number and size. Almost all that apply to me for stocks of bees ask for "the largest hives," and sometimes 20-inch hives are specified. All this is pleasing and encouraging to me, and I mention it to encourage others. Everything indicates advancement and a successful future.

As for honey, I can sell it readily both in the comb and out. I get 1s. and 1s. 8d. per pound for run honey, and 1s. 8d. and 1s. 6d. for honeycomb. I have had greater difficulty this year in selling grapes than honey, and bees are far less costly to keep than vinerias.—A. PATTISON.

OUR LETTER BOX.

EGG YOLKS DARK-COLOURED (E—C).—The appearance you mention may arise from different causes. They are not uncommon in the first eggs of a pullet, but the colour of the yolk is then generally very light. In hard-boiled eggs the outer skin of the yolk is always dark. Our opinion is that the colour will disappear by degrees. We advise you to alter your feeding by the substitution of barley-mel or ground oats for the morning and evening meals. Slake it with water. Give whole corn for the mid-day meal, and discontinue potatoes entirely. They tend always to induce disease of the liver in fowls.

ARTIFICIAL INCUBATION (J. F.).—We know of no special volume on the subject. There is a relative chapter and drawings in our "Poultry-keeper's Manual."

SILVER-SPANGLED HAMBURGERS (Mrs. Forbes).—We should prefer writing to some prizetakers in the north.

DON RABBITS NOT NEST-MAKERS (A. Perrier).—We have never been losers in the way you describe when our Rabbits were properly lodged and attended to. We like the kindling place to be contrived so that it shall be nearly dark and quite out of sight. When the time is at hand they should be supplied with hay, with which they will make their nests, added the flock from their own coats. The does as the kindling time comes on should be moderately supplied with green food and have a little water at times. This keeps them free from fever.

HEN CANARY WITH OVERGROWN CLAWS AND BORN FEET (Ada).—Accidents in various forms occur to hen Canaries when their claws or nails are overgrown. Long nails which assume the shape of a sickle prevent birds hopping freely from perch to perch, or from the perches on to the bottom of the cage; in fact, we have known several deaths to occur solely through birds being unable to free themselves from their perches and wires of the cages. In each instance the bird was found suspended head downwards either from the perch or the wires. Birds when their nails or claws are neglected lose much of that sprightliness of action which cheerful birds should possess when in good health. If birds are to be imprisoned for man's pleasure they should be attended to, for it is impossible they (the birds) can keep down an overgrowth of horny substance either in their nails, and sometimes their beaks, when not provided for in the same way as birds are in a natural state of freedom. But it is rarely that Canaries' nails require clipping until they

exceed the age of one year old. Breeders should be careful in examining the claws of all hens before putting them up to breed from. Accidents may be prevented—such for instance as when a hen suddenly starts from her nest and drag with her the nesting material containing eggs or young hatched birds. The claws when long and twisted cannot be so easily freed from the nest as when short, and the eggs and young are frequently injured through the hen endeavouring to extricate or disentangle her claws from the nest. As a natural consequence long claws tend to bring about sore feet, owing to the unnatural twisting and strain upon the joints of the feet. If there be even a slight accumulation of dirt about the feet soak them in lukewarm water and carefully cleanse them. But we imagine your cages to be kept scrupulously clean, for you say "the perches are clean, so that cannot be the fault" of the sore feet. You ask for a remedy; we are pleased to give one. With a sharp penknife or scissors pare off the superfluous portion of the nails, but be very careful not to cut quite close to the red ray or vein which runs about two-thirds up the claws, and which may be seen by holding the bird's feet against a strong light. If, however, you should by accident draw blood, bathe the feet in salt and water. An occasional bathing of the feet in the solution will also tend to effect a cure of the sore feet. If the bird's feet appear very sore, place until healed some moss or soft hay upon the cage bottom.

DISTRICT FOR BEES (W. M. E.).—Anywhere in Kent would be suitable. About Chislehurst we know of good apiaries.

METEOROLOGICAL OBSERVATIONS.

CANNON SQUARE, LONDON.

REMARKS.

23rd.—Very bright but rather stormy morning; showery about 2 P.M., and occasional slight showers during the afternoon, and very windy; bright starlight night.
24th.—Very fine morning, but much colder; fine and bright all day, but the night not so bright and clear as the night before.
25th.—Raining more or less nearly all day, and very heavily at night.
26th.—Beautifully fine morning, and till 4 P.M., then showery and stormy at night.
27th.—Rain at 9 A.M., but fine before 11; rain again soon after noon, but fine sunset and bright night.
28th.—Rainy early, but sunny before noon; fine afternoon, but showery.
29th.—Rain commencing between 7 and 8 A.M., and continuing very slightly for three or four hours, but very fine afternoon and evening.
Temperature slightly lower than last week. Rain daily, but occasionally very bright between the showers. Sun max. considerably higher than that of the preceding week.—G. J. SYMONS.

COVENT GARDEN MARKET.—MARCH 1.

The market is beginning to feel the scarcity of best fruits, good samples of late Grapes are realising better prices. Among forced vegetables we are well supplied with Asparagus, Sea-kale, frame Potatoes, and French Beans, all of which are making fair average prices. Trade rather better.

THE DAHLIA AND ITS CULTURE.

As the season has now come round again when Dahlia-growers will be turning their attention to the propagation, &c., of that invaluable florist's flower, a few words might not be out of place in connection with the cultivation of the plant which is certainly the queen of the autumn. The Dahlia holds a foremost place in public estimation, as may be witnessed at the autumn shows, where the Dahlia stands invariably come in for a large share of attention and admiration; and looking at the Dahlia from every point of view, whether on the exhibition table, in lines with other subjects, as centres for large beds on grass, in mixed or shrubby borders, or in whatever position it may be placed, its adaptability for such purposes is perfect, and the plants when laden with their symmetrical-formed flowers of almost every shade of colour are always effective.

The roots ought now to be brought out of their winter quarters, and some considerable caution is necessary on their first introduction into heat, more especially if intended to be started in dung beds, than which there is no better place if the heat is not too violent; if so, and full of rank steam, the chances are that many roots will turn soft and decay instead of giving a regular supply of cuttings. If the heat of the bed has declined to 80° or 85° then spread on the surface a slight covering of leaf mould and sand, or any other light material on which to place the roots together, and properly named. When all are placed sprinkle a little of the same material among them, and admit air moderately on every favourable occasion, so that the frame may be kept sweet and dry, when shoots will be sent up in a short time in abundance.

When of 3 inches in length they should be detached from the parent root with a sharp knife, making a clean cut, and be inserted singly in thumb-pots in soil composed of loam, leaf mould, and sand. Very much of the success will depend on the expedition with which the operation is performed, for if the cuttings are allowed once to flag very many of them will rise no more. Water with tepid water, and immediately place in smart bottom heat, when roots will soon be formed. When well rooted the plants should be shifted into rich loamy soil in 4-inch pots well drained. Nothing is more injurious than allowing the plants to remain in the cutting pots until they are potbound. If convenient after this shift give them a slight bottom heat till they are again established, when they should be at once placed in cold frames with plenty of air admitted on all favourable occasions. The object should be now to secure a firm stubby growth, but a strict watch must be kept that frost never reaches them. Towards the end of May the lights must be kept off the plants on all favourable opportunities, so that they may be hardened-off ready for planting the first week of June, which is as early as is consistent with safety in most parts of this country.

Some practise propagation merely by dividing the old roots into as many pieces as there are portions having

eyes, and then potting them in the usual way. I prefer, however, the plants struck as above, believing they give more perfect flowers. Others, again, propagate during summer, taking the side branches and striking them in brisk heat the same as in spring, keeping them in small pots during winter and starting in the usual way in spring, allowing only one shoot to each plant. This is a very safe plan for those who do not succeed well in wintering the old roots.

The preparation of the soil in which the plants are to grow must have particular attention if first-class flowers are expected, and as the Dahlia delights in rich feeding such must be borne in mind when the ground is being prepared. The ground should be trenched in autumn and thrown into ridges, and those who can command decayed turves with plenty of fibre, accompanied with a liberal supply of rich manure, are in possession of the materials that will grow Dahlias to perfection. In April the space for them should be forked over and well broken up again before planting. If for exhibition they are best grown in a square by themselves, and not less than 4 feet apart each way, and in straight lines, the stakes to be placed in position first, and due care taken that the roots are not injured in planting, and that the plants be firmly but not tightly tied to their stakes. When planted each to have a good soaking of water, to be repeated twice a-week if the weather proves dry. Regular syringings on the evenings of hot days will be of great advantage to them. I occasionally use a little soft soap with the water to keep them free from insects. A sharp watch must be kept that thrips does not gain a footing among them, which would utterly destroy the chance of obtaining good blooms.

As soon as the plants are advanced in growth and hot weather sets in I invariably give a heavy surface-dressing of cow manure 3 or 4 inches thick, and line out the alleys between the plants and cover the dung with the soil from the alleys. The leading stem having been kept regularly fastened to the stake, now is the time to add the shoulder stakes, as they are termed in some parts of the country. To each plant four stout stakes are put at convenient distances to support the side shoots to be selected for that purpose, and all others are taken away; and in future all lateral shoots to be thinned-out as well as the flowers, some varieties requiring severer thinning than others, some sorts throwing very rough flowers if over-thinned, while for others thinning is necessary to obtain the flowers of the required size. Due care will also be necessary now to afford the plants abundance of moisture in dry weather, and a good soaking occasionally of liquid manure will be beneficial. To those who may not have access to the drainings from the dunghill I do not know of a better or easier-made liquid for them than guano and soot, which the foliage will bear witness to after the application by the dark hue it will assume.

If for exhibition some means must be used to shade the flowers; and I may here say that I believe many, who have not had much experience, over-shade, which makes the colours washy, and certainly the flowers do not carry so well if they have been subjected to too long

shading. Many devices are used to protect the blooms, the most common of which is, I believe, the garden pot supported on a piece of board. The best shade I have ever used or seen is a round board with a projecting piece with square hole for the stake to pass through, moving upwards and downwards at pleasure, with stiff pasteboard, about 8 inches or so deep, nailed round the circle, and painted white inside; this keeps the flower dry and cool, and protects from the sun's rays, while being open below the blooms obtain a sufficiency of air. A simple and useful mode of protecting the blooms is also shown by the accompanying figures. Fig. 45 (1) represents a piece of pasteboard (old hat-boxes will be quite as good) about 8 inches by 6, less or more. By bringing the two bottom corners together, so as to overlap a little, the pasteboard can be nailed top and bottom to a thin lath of wood, as in (2), which can

Fig. 45.

be tied at the required height upon a tall flower-stick, which should be squared a little to make it set firm; or it may at once be tacked to the stick as shown in (3). These shades will endure heavy rains if the pasteboard be moderately stiff, and will last several years. They have been used for Tulips, Ranunculuses, Carnations, Roses, Pinks, and Dahlias. A diligent search must at all times be kept up to prevent the ravages of the earwig, the greatest pest the Dahlia-grower has to contend with. Small pots with dry moss, Bean-stalks, or whatever may suggest itself to the grower, must be used and looked over daily. As a further protection against earwigs I have occasionally enveloped the flower stems with wadding; for, notwithstanding that earwigs are winged insects, they do not generally fly from flower to flower, and the wadding greatly impedes their ordinary movements, and preserves valuable blooms.

There is also another class of plants that are most useful to the gardener who has broad borders to plant—I allude to the dwarf Dahlias, of which there are many colours from white to bright scarlet, &c., the plants growing from 18 inches, or less, to 2 feet high, and bear their flowers in the greatest profusion.

After the frost has cut down the plants the next care is to prepare the roots for keeping over winter. Cut the plants down at a few inches above the ground, to which fasten the name of each variety. Dig them carefully up, not breaking the roots, and place in flat baskets roots upwards to dry, so that they can be placed indoors at night, and on damp days; when fairly dried they may be stored away where frost cannot reach them. The most successful way of keeping Dahlia roots I have ever seen is to pack them in dry soil; it keeps the roots from shrivelling, and they come out plump and fresh in spring. Of course they should be looked over occasionally to see that none of them are damping.

Appended are the names of a few new and old varieties that I consider well worth growing.

Show.—Andrew Dodds, Alexander Cramond, Acme of Perfection, Annie Neville, Criterion, Charles Backhouse (rather small but good), Crown Prince, Fanny Purchase, Gipsy King, Golden Drop, H. J. Quilter, Herbert Turner, James Service, James Cocker, Leah, Lord Derby, Mr. Sinclair, Miss Henshaw, Mrs. Boston, Ne Plus Ultra, Paisley Paul, Tom White, Walter Reid, W. Keynes, W. P. Laird, and Willie Austin.

Fancy.—Butterfly, Bessie Wyatt, Carnation, Fanny Sturt, Flossie Williams, Flora Wyatt, Gem (Stafford's), Harlequin, Hero of York, Leopardess, Mrs. Bunn, Mrs. Saunders, Mrs. Joy, and Prince of Wales.—J. B. S.

NOTES FROM MY GARDEN IN 1875.

FLOWERS.—AURICULAS.

AMONG the disappointments of the last season was my Auricula bloom: not that I had a bad one, but it was so uncommonly late that I was unable to have any appreciable number of them in bloom for the show, held in connection with the Botanic Society's Spring Show, of our (I fear almost defunct) Metropolitan Floral Society on April 28th. Indeed, in all my experience of Auricula-growing I never knew so late a season, and I have grown them on and off for forty years. For weeks they seemed almost to stand still, and no amount of coaxing could move them on. I remember a few years ago being twitted by some person who had never grown an Auricula for asserting that the date of a show was fixed too early. Why did I not push them forward as other flowers were treated? But they will not stand the treatment that other flowers pass through. Keeping the frames close and putting the plants into the greenhouse does not seem to influence their opening, and certainly does not improve the plants. I know that various plans are proposed for the purpose, but although I have tried them I never saw that they made any appreciable difference.

I adhered to the same plan of growing them as I did last year—viz., not using so rich a compost for the winter season, and then top-dressing with rich stuff (sheep manure) in the spring, and was very well satisfied with the vigour of my plants and their general healthiness. I see, however, in a contemporary, that a very experienced grower in the north recommends top-dressing with not over-rich stuff, nor so old as some people advise. I always thought that this was a cardinal doctrine amongst Auricula growers, that it could not be very well too old or too rich; but it is evident that there are differences of opinion even in this. We have broke away from all the quackeries and nostrums that used to be recommended for these beautiful plants; but I very much question whether it would be wise to go to the opposite extreme and refrain from using manure at all in top-dressing, as seems to be almost the idea embodied in the article to which I refer. The amazing progress which the plants make when top-dressed might be perhaps attained if plainer compost were used, although I doubt it. However, I may, perhaps, give it a trial this season by treating a few in the manner recommended.

As far as the value of the varieties is concerned I have seen but very little to make me alter my views. There are some seasons when particular varieties come out prominently, as will be the case in all flowers and fruits, while there are some which in all seasons hold their own. And we have to remember that it is not with the Auricula as with other florists' flowers. You do not grow a batch of new plants every year, all of which, with the exception of two or three, you discard a few years afterwards; but you may perhaps get hold of one new one in the course of a year or two which may perhaps be better than flowers that have been sixty or seventy years in cultivation, but it is very doubtful. There has been a good deal of discussion, for instance, in the Journal lately as to the merits of two very old flowers—Page's Champion and Taylor's Glory. Does it not seem strange that these flowers, which were in cultivation before many of us were born, should still hold such a prominent place? Mr. Glenny has been quoted as an authority, although his authority has been repudiated. I should, by-the-by, not have liked to have done so if G. G. had been alive. I should like to quote one whose authority is second to none, my deeply mourned friend the Rev. G. Jeans; and although it was written fifteen years ago and I am referred to, yet I cannot forbear quoting it. After enumerating the varieties in growth he says, "And now to conclude. Where are we to look among them all for the type of a green edge such as we want? I confess I know not. Is not Page's Champion the best we yet possess? 'D.' of Deal thinks it is. 'Q' (the Rev. John Bramhall) says it is, and I am forced to admit that it is; and therefore it is the best, for who in the Auricula world would pit his dictum against such a trio? But this I say, Shame to seedling raisers if it is; but I believe it is notwithstanding." As to Glory, the following in his description in "Gossip for the Garden" for 1860—"The best of Taylor's then, and perhaps of all white-edged Auriculas. Pip a circle, flat; edge pure white; colour light purplish plum,

of good proportion; paste circular, substantial; eye light yellow; anthers hidden. Foliage smooth, handsome, evenly mealed. First-rate trusser." And we have had nothing since then to displace it. Heap's Smiling Beauty was in cultivation then. Moreover, as a general rule it is not so flat as Glory, and there is a dash of grey in the edge which takes away from the perfect whiteness which distinguishes Glory. We hear faint echoes from the north of other flowers which are to beat those we have, but we may at any rate hold our judgment in suspense. I find that George Levick, for instance, which is said by some to beat George Lightbody, has had doubts thrown on its pre-eminence by no less an authority than the Rev. J. Tymes, a first-rate grower.

It is a mystery to me that this lovely flower should have so almost entirely gone out of cultivation in the south, while in the north it still holds its own. There died the other day at Shirley near Southampton one whom I remember well in days long since past—Mr. Ginger—as amongst a coterie of growers of whom John Dickson of Acre Lane, Brixton, was *facile princeps*, and now the fingers of one hand are enough to enumerate all of us in the south of England. I am sure it is a fallacy to suppose that Auriculas are difficult to manage. There are some kinds, doubtless, which are miffy and slow to increase, or else why after sixty years should Booth's Freedom be almost extinct, and Page's Champion, Taylor's Glory, and Leigh's Col. Taylor be so difficult to obtain? But these are exceptions. Such kinds as Waterhouse's Conqueror, Headly's George Lightbody and Charles Edward Brown, Lightbody's Richard Headly, Cheetham's Lancashire Hero, Campbell's Lord Palmerston and Pizarro, Masters's Mrs. Sturrock and Eclipse, and many others are not only not difficult to grow, but readily increase. They require care, no doubt, but so does everything that is to be done well; but they will amply repay all the care that may be bestowed on them. I have digressed a good deal from my own culture in this rambling paper, but love for the flower must be my excuse.—D., Deal.

ROSES.

On page 131 Mr. Camm gives a very melancholy account of own-root Roses, and the time taken to grow them. My experience in raising Roses from cuttings differs very considerably from Mr. Camm's. Before going further I must state that the soil of my garden is a deep sandy loam, and that my latitude is a few miles south of London.

At the end of September or beginning of October the cuttings from ripe wood are carefully prepared, and planted in rows in one of the most open plots in the garden without manure. By the following February it will be found that each cutting has formed a mass of incipient roots round its base. The plants must now be kept from the drying influence of sun and wind by hurdles and mats. Should the young shoots at the top be allowed to flag, the tender roots will be injured and the plants die. They must be frequently watered in dry weather. When well rooted the covers may be removed, but the watering must be kept up.

By adopting the above treatment the majority of my cuttings have made good plants by the following summer, and have afforded an abundance of blooms, and by October they will have made strong shoots, many of them over 8 feet long. In November the best are planted—with a good ball of mould round a mass of fibrous roots—into the Rose beds, and those that would make "weary work" in forming good bushes are consigned to the rubbish heap. Those planted out are severely pruned early in the following spring, and form fine plants during the summer. Some sorts succeed better than others; such hardy kinds as Charles Lefebvre, John Hopper, Victor Verdier, Comtesse d'Oxford, Madame Victor Verdier, &c., seldom fail.

I believe one cause of disappointment is planting the slips in the shade, as recommended by many. To keep them damp and in the shade, in the spring when commencing to throw out their tender roots is necessary, but when the roots are safe a shady corner is the worst possible place for a Rose nursery. It will take a long time to make strong plants in such a position, therefore I consider it much better to plant the slips in a plot selected for its exposure to the sun, and to give water and shade when required. I find that short slips often fail in consequence of their making growth on one side only, and consequently dying on the other.

As to the proper time for putting-in the cuttings there is a great deal in the remarks of "PHILANTHOS," who, in the Journal

for July 29th, 1875, recommends the summer. Immediately after my reading his opinion I went into the garden to give the plan a fair trial, but unfortunately was too late to find many ripe stems that had not thrown out side shoots; however, I found a few, and they were soon cut-up and in the ground, and protected from a scorching sun by cabbage leaves. All these were well rooted by the autumn, and had made short shoots, which remained healthy all the winter, notwithstanding the severe frost. They appear ready for a good start this spring, and I believe will be quite a success. This year I intend to make my slips as soon as the first blossoms are over and before the second growth commences, and if space will be granted in "our Journal" I will report the results.

It will at once be seen that very few cuttings can be obtained in summer compared with those that can be made from the numerous strong shoots ripe in the autumn; but I think that the success of the summer cuttings, and the small amount of trouble they give, will be found to compensate for this deficiency.

The question has been raised as to whether the quality of the blooms from plants on their own roots differ from those grown on the Manetti roots. On this point I should like further information, and hope that the readers of the *Journal of Horticulture* will have the benefit of the experience of those who grow Roses in both ways, and at the same time it will be important to know what soil the plants are grown in. As to the difference in the trouble caused by planting cuttings on the one hand and budding on Manetti stocks on the other, the two processes are not to be compared. A hundred cuttings can be prepared and planted in a very short time, but I am afraid to say how long it takes to bud the same number of Manetti stocks, leaving out the question of raising the stocks.

I once read in a newspaper of a man who for some offence was sentenced to three months hard labour. The man so sentenced, replied: "Thank you, sir, I can do that little job on my head." Now, I suppose it is men with this peculiarity of being able to work in the above-named position who are hired at the nurseries to bud Roses on Manetti stocks. The man has to remain on the surface of the earth while he carefully performs a delicate operation below that surface. I have so budded a few every season for some years past, and I must confess that I do not like it. Yet I must say that I would willingly go through the work and much more for the queen of flowers if the question of quality should be decided in favour of Manettis.—W. G.

A NEW CLASSIFICATION OF APPLES.

BY ROBERT HOGG, LL.D., F.L.S.

I OFFER this system of classification with a consciousness that, like every other which has been proposed, it is not perfect. No system is perfect, and so long as science continues to advance with such rapid steps the founders of systems must change and advance also. It was my wish to have published it in the last edition of my *Fruit Manual*, and the printing of that work was delayed so long in the hope that I should have been able to have done so that I was compelled to go to press with it before I had brought my classification to a state which was satisfactory to myself. I should have preferred postponing the publication of it even now till I had spent more time on the application of its principles, and thereby proved the correctness of my views; but some friends, whose opinion I esteem very highly, urged its publication, and I have consented in the hope that, now it is in the hands of the public, they also will have an opportunity of applying its principles, and thereby assist me in making it more perfect and complete than it is at present.

One of the greatest difficulties pomologists have had to contend with is the want of a classification of the varieties of Apples and Pears by which they can ascertain the names of varieties in the same way as the botanist is enabled to discover the name of a plant when it is unknown to him. Every other kind of fruit has up to the present been arranged according to characters, which are sufficiently distinct and permanent to make the classification of real service; but of the Apple and the Pear there is none which can be worked with any kind of assurance that it will lead to the desired result. It is not that no attempts have been made to form a classification. On the contrary, Dial, Dochnahl, and Lucas have each produced one, each of which is a modification or altered form of the other; but the characters upon which they are based are to my mind too varying and not sufficiently apparent to render them so

useful as could be desired. In my work on the Apple, which was published five and twenty years ago, I gave a kind of classification to assist students in pomology to ascertain the names of the different varieties; but it has never served that purpose. Previous to this I had attempted to apply Diel's system and failed. Ever since that time I have been assiduously observant of every character in the structure of the Apple which I thought served as a basis for a classification, and at last I fixed upon those which I have accepted as the principles of the new system which I am now about to describe.

The characters upon which this system is based are well known, and have been noticed in descriptions of fruit so long ago as by Diel and other German pomologists; but just as the pre-Linnæan botanists observed the stamens and pistils in plants, and entertained certain views with regard to their functions without employing them as bases for classification, so has it been with the pomologists who, while aware of the presence of the characters, have hitherto overlooked them as being applicable to classification.

For some years past I have endeavoured to apply the characters I have now adopted. The light I had at first was small and dim, but by repeated application to the subject every recurring fruit season I began to see the foundation of what has now grown up to the structure which I now offer to the world.

My reason for not giving publicity to it before this was that I wished to work it thoroughly before I committed myself to it. To do so I have procured in various years collections of fruits from different parts of the country, from different soils and climates, and also at different seasons of the year, and in every case I was gratified to find that the characters which I observed in each variety of fruit were equally well marked in that variety from whatever district, soil, or climate it came, or at whatever season the examination took place. For instance, Wyken Pippin from Tweedside, from Chiswick, from Sussex, from Worcester, from Somerset, and from Devon invariably presented the same characters of eye open, seed-cells closed, calyx-tube conical, and stamens median. This I merely give as an example, and it is applicable in every case.

I must remark, however, that in this as in every other classification of natural objects the characters are not always constant, and there are varieties which refuse to submit to any scheme of man's devising. Nature refuses to be bound, and we must adapt our ideas to her laws. In every system it is so, as the botanist well knows; when he would class plants into those which are hypogynous, perigynous, and epigynous, he finds there are some that reject his interference and assert a double alliance. And so it is with fruits. There are those in which some varieties have the eye open or partially closed, seed-cells of the same character, calyx-tubes in which it is difficult to determine whether they are conical or funnel-shaped, and stamens which waver between a marginal and median position, or a median and a basal. But these are difficulties which are easily got over, as I shall show further on.

The characters which I have adopted as the basis of this classification are the eye, the seed-cells, the calyx-tube, and the stamens. These supply the primary and most important divisions; but they may be extended and broken up into fruit round, roundish, or oblate, and fruit conical, oblong, or ovate, and these for convenience may be farther divided into pale, coloured, and russet. I will now treat of the leading characters.

1. *The Eye*.—This is the pomological term used to signify what botanists call the sepals or limb, and mouth of the calyx. In French it is called *cil*.

If we examine a great number of varieties of Apples we find that in some the eye is wide open, and the segments quite re-

Pippin, and Court of Wick; and it is illustrated in the annexed fig. 48. In many cases the segments are erect and spreading or reflexed at the tips, and this form of structure also leaves the eye open though not so much so as in the previous examples. This form is shown in fig. 46. Between the spreading and the erect open eye there are many gradations which will be remarked by any observer who examines the different varieties.

The other form is the *closed eye*, fig. 47. It will be observed in this case that the segments are erect and connivent at the tips, forming a small cone. In some cases of this form of closed eye the tips are spreading; but there is another very distinct form of the closed eye in which the segments are quite flat and convergent, closing in the eye like a trap door in five divisions, as is seen in Trumpington. These two characters of *Eye open* and *Eye closed* I propose to employ as my primary divisions.

2. *The Seed-cells*.—These constitute what is popularly called the core of the Apple, and contain the seeds or pips. They are usually five, but they vary in number, and are occasionally

Fig. 49.

Fig. 50.

three, four, and even six. They differ very much in structure, and are either open to the axis of the fruit or closed; and between the closed and the wide-open cells there are as many gradations as in the closed and open eye. Fig. 51 represents perfectly closed cells; fig. 50 those that are open, and fig. 49 those that are wide open. In the last all the Codlins are to be found, and varieties having the Codlin character.

The Seed-cells form the second great divisions of my system, which are distinguished as *Cells open* and *Cells closed*.

3. *The Calyx-tube*.—In making a longitudinal section of an Apple in a line through the centre of the eye to the stalk a more or less deep cavity will be observed under the segments

Fig. 51.

Fig. 52.

of the eye and between them and the core. This is called the *Calyx-tube*, or *Kelchröhre* of the Germans. It is of very varied form, but all of these are modifications of two, or perhaps three, which may be regarded as distinct, and these I have called the *conical* and the *funnel-shaped*. As in the cases of the open and the closed eye and the open and closed cells these run into one another, and there are instances in which

Fig. 46.

Fig. 47.

Fig. 48.

flexed, in some cases so much so as to be quite flat on the surface of the fruit. This is very apparent in Blenheim Pippin, Wyken

Fig. 53.

Fig. 54.

it is difficult to distinguish to which of them the individual belongs. Figs. 52, 53, 54, 55, 56, and 57 are illustrations of the conical tube, some being wide and deep and others narrow and short. Figs. 58, 59, 60, 61, and 62 represent the various

forms of the funnel-shaped tube. The third form is the cup-shaped, which very rarely occurs, and is a short shallow variety of fig. 55.

Fig. 55.

Fig. 58.

The Calyx-tube is the character on which the third division is based, and is divided into CALYX-TUBE CONICAL and CALYX-TUBE FUNNEL-SHAPED.

Fig. 57.

Fig. 59.

4. The Stamens.—These are the little bristle-like bodies which are found forming a fringe round the inner surface of

Fig. 59.

Fig. 60.

the calyx-tube, and it is on the position they occupy that the fourth character of this system is founded. On examining a number of different varieties of Apples it will be seen that the stamens are not always in the same position. Some will form a fringe immediately under or near the base of the segments, as represented in figs. 58, 57, 59, and 60, and these I call *marginal*. Others occupy a midway position between the margin and the base, as in figs. 55, 56, 58, and 62, and these are called *median*; and a third are situated near the base, as in figs. 52, 54, and 61, which are termed *basal*.

Taking the position of the stamens as my fourth great division we have—1, STAMENS MARGINAL; 2, STAMENS MEDIAN; and 3, STAMENS BASAL.

To prolong the subdivisions even beyond this point to which we have arrived, we can have—1, Calyx-tube short conical, as in fig. 53, and deep conical as in fig. 52. Then we can have short funnel-shaped, as in fig. 62, and long funnel-shaped as in fig. 58. These may again be further divided into—1, Fruit round, roundish, or oblate; and 2, Fruit conical, oblong, or ovate.

Fig. 61.

Fig. 62.

I have already called attention to the changeableness of the characters in some varieties; how in the cases of the eye and the cells some exhibit them open or closed, or intermediate between the two; also in the interchangeable form of the calyx-tube and the positions of the stamens. In the following classification I have provided against any confusion arising from this cause, and have given additional references when a variety is to be found in more than one division. For example, in Scarlet Nonpareil the eye is sometimes open and sometimes

closed, though the calyx-tube is always short funnel-shaped, and the stamens marginal. This variety is therefore placed in Class 1, section two (§§), and division one (†); but to provide for the case of the eye being closed, it is entered thus—“Scarlet Nonpareil iii., §§, †,” showing that it is also found in Class iii., section 2, and division 1.

It is important that perfect specimens of fruit be used when the classification is applied, and especially that the eye be perfect; and to observe the calyx-tube correctly the longitudinal section should be made directly through the centre.

CLASSIFICATION OF APPLES.

Class I.—EYE OPEN (figs. 46 and 48). CELLS OPEN (figs. 49 and 50).

§ CALYX-TUBE CONICAL. Hambleton Deux Ans
† Stamens marginal (figs. 53 and 57). Ribston Pippin, iv. §§ ††, ii. §§ ††

ROSES ON THEIR OWN ROOTS.

MR. CAMM has spoken disparagingly of Roses growing on their own roots, and, moreover, when they are required for pot culture. I write not as a rosarian but as a gardener, and I am not willing that Mr. Camm's opinion should carry undue weight. I do not grow Roses for exhibition, but I have grown them for many years for home enjoyment. I have grown them in pots and out of pots, on Briars, on Manettis, and on their own roots. A few varieties of Roses do not strike freely from cuttings, but most of the Hybrid Perpetuals do so readily, and they also grow luxuriantly.

For cultivation in pots I prefer Roses on their own roots. I have never cut such fine blooms of John Hopper as from plants which had been raised from cuttings. The colour is deeper and the perfume more powerful than on budded plants. That fine old forcing pot Rose Baronne Prévost is larger, brighter, and infinitely sweeter when grown on its own roots than when nurtured by any foster-parent. Another sweet Rose—yes, the sweetest Rose of all—the old Provence Cabbage, is deprived alike of its agreeable form and delightful odour by being budded on either the Briar or the Manetti, and especially the former. Général Jacqueminot is more glowing in colour from cuttings than when budded on other stocks. Bessie Johnson is decidedly sweeter when she forages for herself than by trusting to any dog to bring her a bone. Charles Lefebvre, Alfred Colomb, Baronne de Rothschild, Marguerite de St. Amand, Marie Baumann, Madame Eugénie Verdier, Madame Charles Wood, and other sterling sorts I have grown from cuttings in the most satisfactory manner.

I am positive that many Roses are sweeter when grown on their own roots than when worked on any stocks, and the colours are also brighter. I should like to try Mr. Turner's new Rose, the Rev. J. B. M. Camm, on its own roots; it is deliciously perfumed. I shall not hastily mount this Rose on stilts lest it should lose influence. I rather fear its prototype will also lose influence if he mounts Briars to denounce humble, useful, own-root Roses, and especially when the plants are required for growing in pots and for forcing. On the matter of producing high-class exhibition blooms I bow submissively to Mr. Camm, but for forcing Roses in pots I have a suspicion that our friend has yet something to learn.—A NORTHERN GARDENER.

APPLES AND APPLE TREES.

OF late something has been said in our Journal about Apple trees. If "YORKSHIRE GREENING" could furnish us with any information respecting an Apple called Yorkshire Robin, a noted but no doubt a local Apple, which was much prized many years ago, I for one would esteem it a favour, as I fear some of our old favourites are becoming things of the past. I am able to give a better account of our useful old friend the Hawthornden Apple than your correspondents. I have at the present time in use as fine examples of the above Apple as need be seen, entirely free from scab, and to all appearance likely to keep for some time to come. We have here two kinds of soil, one a light loam resting on a gravelly subsoil, and in it has been growing for the last fifty or more years a Hawthornden Apple tree always kept as a bush, so that there is nothing very new about bush-fruit culture. The tree takes up very little room, is in good health, and free from canker as near as can be, and brings us a crop of fine fruit annually. I

do not think it has ever been disturbed at the root since it was planted. It is pruned and dug about yearly, and to all appearance it is likely to go on for many years to come. I cannot say what stock it is worked on.

The other soil is a strong tenacious loam resting on a clay subsoil, and in an orchard are planted two Hawthornden Apple trees of about fifteen years' growth from the graft on the Crab stock. They are in the pyramid form, giving us abundant crops of fine fruit, in the best of health and quite free from canker. They are planted in grass and have not been disturbed since they were planted, receiving a little manure occasionally to help the grass as well as the trees. They are regularly pruned, and to all appearance likely to do us good service for some time to come. Many Apples may be substituted for our old friend, but I find it a very useful kind.

I said in our Journal some time ago that fruit trees ought to be as numerous as Thorn bushes, and Apple trees should have a first place, being of the most useful of hardy fruits. There is no difficulty with careful selection and a little trouble in having them for use the year round.—M. H., *Camphill, Bedale, Yorkshire.*

SWEET-SCENTED FLOWERS.

AMONGST the many advances of the present day there is one which cannot have escaped notice, and that is here seems the greatest possible freedom offered for people finding fault with each other or with existing things. Old notions or customs are attacked on every side; sometimes, however, the attack is to their advantage, as their good qualities come out all the brighter through the ordeal. It is the fashion now in a great measure to ignore practice in favour of what is termed philosophical principles. Many things threaten to be turned upside down; but there is one subject, and that too in a branch which critics have not turned their attention to yet, or but to a slight extent, and yet it is one not to be disregarded in the economy of the world. The subject relates to one of the most refined branches of horticulture, and one more especially under the patronage of our lady friends, that it may appear bold in my attacking a department so likely to be ably defended. The matter that I wish to make further inquiry upon is this: Are all scented flowers hurtful to health, and how many are there that are sweet-scented?

Perhaps it will be well to take the last part of the question first. Some, among whom I class myself, would limit really sweet-scented flowers to a mere fraction of the number which are generally classed in that category. At the time I write the Hyacinth is fashionable. What is the general opinion of this plant? Can its flowers be called agreeably scented or the reverse? A mere single sniff is not sufficient to form an opinion, as the sense of smell is likely to be governed by the pleasure which the appearance of the flower imparts to the eye. I would submit scented flowers to some blind person, as one likely to give an honest verdict. We go on to other plants and ask the question, Are such flowers as Stocks, Pinks, the Hawthorn, Carnations, and sundry other of the Dianthus family "sweet-scented," or are they merely "smelling?" I confess being of opinion that the last-mentioned term is all they deserve, but I may be fastidious. Then we have *Ageratum mexicanum*, French Marigolds, Poppies, *Humea elegans*, Heliotropes, and some others that are highly offensive, at least I think so. Neither can that most powerful-scented of ordinary shrubs, the *Daphne Laureola*, be called sweet, still less so the Privets and Syringas; they are powerful in the scent given off, but not sweet. I hardly know what opinion to give on the Wallflower and Cowslip, perhaps a neutral one; but the Primrose has a higher claim to be regarded as sweet, and Violets, Mignonette, Mint, and *Aloysia citridora* cannot well be found fault with. To these may be added a sprig of Lemon Thyme, but I fear all other ordinary garden herbs must be rejected. Of course it would be treason to say anything against the Rose, and let it be fairly understood that as a scented flower I am willing to place it first, with Violets and Mignonette close to it; and if any two of these were present I do not think any more scented flowers are wanted. If, however, there be no sweet-scented flowers to be had, a sprig of the sweet-scented *Aloysia* is very telling, and mixed with Dahlias in a stand perfume is added to beauty.

I am not sure that a great number of scented flowers are advisable anywhere excepting in the open air, where many of them give off the most agreeable perfume. Wallflowers are most agreeable after a slight shower, and the same may be

said of Stocks, and the scent of a Gorse-covered common when in bloom is not offensive; but a large breadth of the common Privet or Syringa emits an oppressive perfume. Nothing adds more to an agreeable country walk in spring than the scent given off by Violets on a sunny day; and a neat little nosegay of Violets and Primroses, with a few leaves of both as an edging, is a bouquet fit for a queen. I fear that I have made a bold onslaught on what is often regarded as choice and precious, in refusing to acknowledge certain plants sweet-scented that catalogues tell us are so.

Might I now ask some one to give us a chapter on the other department—namely, Are all scented flowers hurtful to health, and to what extent are they so? I should not expect that while flowers are in the open air any harm whatever can be done; but highly-scented flowers when confined to a room must vitiate the atmosphere of that room. In thus calling attention to scented flowers I wish to suggest that many which now claim to occupy that position have no claim to sweetness at all, and that the term "scent" is very often misapplied. I fear the public are too apt to accept what has been told them in this matter, and thus a flower that has once obtained the reputation of being a sweet-smelling one retains that character, although perhaps not one in ten likes it. I should like to hear what others have to say upon the subject of sweet-scented flowers.—J. ROBSON.

WITLOOF.

WE take the earliest opportunity of warning our readers against a false impression which has sprung up with regard to Witloof. We are informed that some seedmen are already selling seed of the common Chicory, which they represent to be identical with Witloof. Like all other cases of substitution, the purchaser will find out when it is too late that he has been deceived. The two plants are perfectly distinct varieties of the same species, as much so as the common Rape and the Swedish Turnip; and the gardener who trusts himself in such hands will look as foolish next winter as the farmer would who listened to the man who told him that the seed of common Rape would produce "Swedes." The Witloof is, in fact, a hearting Chicory, and is one of the varieties of that plant which is grown for its large roots as a substitute for coffee. Mr. Van Houtte well describes the distinction in the last issue of the "*Flore de Serres*." "Everyone knows Barbe de Capucin, the common salad of the Paris markets, and which is produced by common Chicory. In the latter the roots are slender and not thicker than a blacklead pencil, terminated by long, narrow, white leaves, 8 inches or more in length. Barbe de Capucin which does not possess these characters is not to be recognised. In the Witloof, on the contrary, the root is short and thick, and bears a mass of erect, broad, thick, imbricated leaves, and forming a small elongated solid heart, which reminds one of the heart of a *Cos Lettuce*. Except in the mere fact of being blanched, the Barbe de Capucin and Witloof are in all points the opposite of each other; length and slenderness on the one hand, and shortness and bulk on the other, they present to us the two extremes of the series of blanched products which can be produced by the Wild Chicory."

SURFACE MANURING.

THERE is no reason why Mr. Graves and "PRACTICAL GARDENER" should fear that on this or on any other question their observations of facts should be at variance with science. Science is built upon facts, and I only ask that the observations should be accurate, so that the facts may be certain. In the instance under discussion there is no scientific reason for looking on the facts recorded by these gentlemen with distrust.

Animal manure gains something and loses something by lapse of time. Its crude constituents are first resolved into forms capable of assimilation by plants, and are next gradually dissipated in the air or washed away in the soil. A great part of Mr. Lawe's invaluable experiments at Rothamstead have been directed to ascertain the extent and rapidity of this last process, and their result may be said to be that animal manures are less easily washed out of the soil than mineral manures. But this leaves untouched the question, important alike to farmers and gardeners, How far it is better that decomposition should proceed on the surface rather than in the soil.

It would be very interesting if Mr. Graves and others would record fully their experience on this head. Do they apply

the manure fresh from the stables, or do they find it best that it should first be half or wholly rotted-down? Do they find any difference according as the application is in summer or winter, in dry weather or in rainy? Perhaps Mr. Pearson would also favour us with his further experience on a practice of which he is in some measure the originator. Every observation, whether leading to success or failure, is of importance and should be recorded, for it is only from a comparison of results under different conditions that we can arrive at any trustworthy principle for our guidance.—J. B. K.

CHRYSANTHEMUMS.

I HAVE for many years given a good deal of attention to these most beautiful autumn flowers. I had not the advantage of seeing the Temple Chrysanthemums this autumn; but while I am aware that the large blooms produced there are on long and rather leafless stems, I take leave to differ from "A COUNTRY GARDENER" in his opinion volunteered to the lady to whom he introduced himself as to the impossibility of obtaining large blooms on short stems, and also as to the fact that they cannot be made available for a small greenhouse. It is difficult I admit, but by no means impossible, and it requires much more real skill and attention to produce ten or twelve good blooms on a plant with the foliage down to the pot and about 24 inches high, than it does to grow a plant as long as a fishing-rod with one or two enormous flowers. But I have seen such plants grown in a small greenhouse belonging to a lady in whose employ I am, and I hope to see more of them this autumn, in spite of a very regular demand for various other items required by the cook.

The secret of obtaining such plants as my employer likes is rapid growth, careful attention to watering, a full and constant exposure to the sun, with a liberal supply of manure water until the time arrives for the plants to set their buds, when it must be withheld or they will go blind; and above all the cuttings should not be struck before the middle or end of April, and stopped only once—when the lower laterals are well developed.

I put two or three plants in a 10-inch pot, and these properly managed will give three or four good blooms each, nine to twelve for each pot. I am by no means always satisfied with the result, and admit the mop-handle plan is easier and more certain; but one is simply a hideous dry stick with a fine bloom on the top, the other a beautiful plant both in bloom and foliage.—COTTAGER.

THE ROYAL HORTICULTURAL SOCIETY.

YOUR report of the meeting of the 24th February does not quite give the sense of what I said, or at least meant to say. It should have run thus:—That much had been said about a house-to-house canvass to bring in new Fellows living in the neighbourhood of the gardens, but in my opinion the true policy of the Council was to canvass the country for new horticultural Fellows, giving them only horticultural privileges, and charging them only one-guinea subscriptions, and that this proposal had been laid before the Council, and was at full length in the *Morning Post* that morning (24th February).

Now that I am writing may I add, *apropos* of some remarks at the end of the President's speech, page 177, that having since 1873 constantly urged the guinea-subscription plan being tried, I have had time to realise its difficulties. These, I believe, will be most easily met (as is usually the case) by a simple broad line of policy. I would have two classes of Fellows—those who want general privileges and those who want only horticultural privileges. The first should pay, as at present, £4 4s. and £2 2s., the latter one guinea. If the Council fear that the present prop might be shaken before the new one was in its place they might make the guinea fellowships dependant on a sufficient number of suitable applicants. I believe, on the contrary, that some of them who came in on horticultural privileges would change to general, and that the present miserably meagre attendances to see the choice flowers exhibited at the Wednesday meetings must discourage exhibitors, and that more admirers would bring still better shows, and that this would act and re-act. Judging by the articles in the *Saturday Review*, *Pall Mall Gazette*, and *Punch*, public opinion appears awakened to the fact that the present use of the South Kensington garden is hardly a legitimate one. If the gardens were the head quarters of a Society which really represented national horticulture the title to the ground would be very

different from the present one, or from one given by an income of £10,000 a-year from residents at South Kensington.—GEORGE F. WILSON.

INFLUENCE OF LIGHT AND AIR ON LADY DOWNE'S GRAPE.

THIS Grape, notwithstanding its excellent reputation as generally the best late-keeping Grape in existence, has, in instances which have come under our notice, met with great disfavour on account of its thick leathery skin and deficiency in flavour. To a very great extent this character is generally correct, until at least far on in spring, when it develops to some extent a Muscat flavour. During the past winter we had an opportunity of tasting this Grape, both in December and February, grown under the influence of as much light and air as it could possibly be subjected to in this country, in a large very light span-roofed house, with a maximum of glass and a minimum of woodwork, and both direct and diffused light to an extent which is rarely met with; and so excellent in flavour, and so thin and actually tender in skin, were these Grapes, that, had we not known that they were Lady Downe's, we never could have believed that it could be grown with these points so much modified and improved. They were, in fact, rich sweet Grapes with comparatively a thin skin devoid of toughness. No other influence could be credited with the transformation but the extreme light and airiness of the structure in which they were grown.—(*The Gardener*.)

PORTRAITS OF PLANTS AND FLOWERS.

CYPripEDiUM ROEzli. *Nat. ord.*, Orchidaceae. *Linn.*, Gynandria Monandria.—Flowers yellowish green, purple-marked. "*Cypripedium Roezli* is a native of New Grenada, where it was found by Roehl on the banks of the Dagua river, which, according to Regel, occupies a valley between two ranges of the Andes. I find, however, no such river on the map, but a small town of Dagua on the western declivity of the Andes near the Bay of Choco. The specimen flowered at Messrs. Veitch's establishment in January, 1874. It is said to flower perennially and profusely, a statement inconsistent with the habits of any plants in continuous health, but which, if taken with the caution to be used in accepting the laudatory advertisements of choice plants, may be regarded as evidence of its being a very free flowerer."—(*Bot. Mag.*, t. 6217.)

ANTHURIUM SAUNDERSII. *Nat. ord.*, Aroidae. *Linn.*, Triandria Monogynia.—"*Anthurium Saundersii* was received from the rich collection of W. W. Saunders, Esq., but with no information as to its native country, under the name of *A. coriaceum*, *Lind.*; but it widely differs from Endlicher's plant of that name, and approaches more nearly to *A. Ottonianum*, *Kunth*, also a native of Brazil, and to one called *A. jatrophaeifolium* in the Kew collection, a name I have not found in any publication."—(*Ibid.*, t. 6218.)

EPISCIA KETTEROPUS. *Nat. ord.*, Gesneraceae. *Linn.*, Didynamia Gymnospermia.—Flowers pale rose. "Introduced from New Grenada by Messrs. Veitch, who sent the plant in flower in March, 1874."—(*Ibid.*, t. 6219.)

TALINUM ARNOTII. *Nat. ord.*, Portulacae. *Linn.*, Dodecandria Monogynia.—"This is one of a collection of plants of a very remarkable habit, which was sent to Kew in 1867 by the Hon. David Arnot, then Commissioner for the Griqua States, and residing at Eskdale, Albania. For the most part they presented more or less cylindrical or spindle-shaped woody stocks of almost stony hardness, which serve as reservoirs of moisture and nourishing matter during the scorching droughts of the dry stony district they inhabit. Of these some remained for several years in the stove before they showed any signs of life, and when they did so they proved to belong to very different natural orders. The genus *Talinum* is represented in South Africa by a widely diffused species, the old *T. cafferum* (to which the present is perhaps, too, nearly allied), which differs in the narrow leaves contracted at both ends, and, judging from dried specimens, the much smaller flowers. The only other Old World species is *T. cuneifolium*, *Willd.*, a native of tropical Africa and Arabia, which extends eastwards into western India."—(*Ibid.*, t. 6220.)

BOUCHERA PSEUDOGERRAEO. *Nat. ord.*, Verbenaceae. *Linn.*, Didynamia Angiospermia.—Flowers purple. "An annual herb, often becoming almost shrubby at the base, widely distributed throughout the warmer parts of the South American continent, from Peru to the province of St. Paul in South

Brasil, inhabiting woods, waste places, and rubbish heaps."—(*Ibid.*, t. 6221.)

LILIUM PARKMANII.—"The plant, as grown by Mr. Waterer from a not over-vigorous bulb, was about 2 feet high, the stems slender, and each bearing a solitary erect, or nearly erect, flower, though it is probable, as both its parents when well grown produce a branched inflorescence, that this hybrid may have the same habit. The leaves were dark green, numerous, alternate, and ovate acuminate in outline, a good deal resembling vigorous leaves of *L. speciosum*. The flowers were very large; the perianth segments, when straightened, being about 14 inches in length, and the whole flower, as reflexed, having a breadth of 8 inches, the petaline segments 4 inches broad, and the sepaline one somewhat narrower. The basal half or more of the segments was diffused with rosy crimson, most deeply so near their median line, this tinted portion being also spotted richly with deeper crimson spots, and bearing papillae (some of them a quarter of an inch long) of the same rich hue, the tints, as in many other Lillies, having a sparkling brightness which cannot be reproduced upon paper. The upper end of the segments and the margin were of a clear white. The anthers were nearly an inch long, and bore chocolate-coloured pollen, while the style, with its purple stigma, was about an inch longer than the somewhat spreading stamens. The fragrance of the flower was delightful, the odour being sweeter and more delicate in its nature than that of *L. auratum*, but more powerful than that of its mother-parent. This remarkable hybrid, between *L. auratum* and a deep-coloured variety of *L. speciosum*, was raised by Mr. Parkman, the President of the Massachusetts Horticultural Society."—(*Flor. and Pom.*, 3 s., ix., 49.)

HARTSHOLME HALL,

THE SEAT OF JOSEPH SHUTTLEWORTH, ESQ.

THIS is one of the new gardens of England, worthy of note, not by its extent, but by the skilfulness which is apparent in its formation and arrangement, and the good management which it has received from the owner and the ability of the gardener.

The present condition of Hartsholme is a monument of perseverance—a triumph of art over nature, whereby a desert has been transformed into a garden and a barren soil made fruitful by the investment of capital, taste, and labour.

Less than twenty years ago the site of this garden was little better than a barren waste—a low-lying gravelly brash, unequal to support agricultural crops, and where Willows, by the water, and clumps of Scotch Firs were almost the only representatives of permanent vegetation; but now it is one of the most flourishing, as it is one of the most beautiful, gardens in the district, singularly rich in Conifers, shrubs, and ornamental trees in superb health, and, considering the time they have been planted, nothing short of marvellous proportions. That this is so may be perceived from the fact that the shrubs were only planted in 1862, and now the Deodars are 30 feet high and 20 feet in diameter. Wellingtonias are of the same height, and other shrubs and trees have made equally remarkable progress.

Mr. Shuttleworth was no doubt influenced to select this barren wild for his residence by its containing a fine natural lake nearly thirty acres in extent, the reservoir which supplies the city of Lincoln with water. If its banks were bare and the land adjacent sterile, these were only impediments to be overcome, and the greater the obstacles the greater the honour of successfully surmounting them. The owner of Hartsholme long before he erected his mansion had splendid proof of the power of perseverance, and had achieved success in aiding to establish one of the greatest and most substantial commercial establishments in the kingdom. The names of Clayton & Shuttleworth are familiar to every civilised country. They have, by their portable thrashing engines and other introductions, revolutionised agriculture; and when the history of the firm comes to be written it will in truth be found a "wondrous tale." The man who had shared in making from the very foundation a position so commanding as is the undoubted magnitude of the operations in which he shares, was not likely to be deterred from making a garden however flat might be the site and sterile the soil.

The south side of the lake mentioned was selected for the site of the residence, and a spacious mansion in the Elizabethan style was forthwith erected. The ornamental grounds are arranged along one side and end of this lake, the opposite

bank being clothed with Firs and the wide-stretching woods of Skellingthorpe. In the front of the Firs and near the margin of the lake are fine clumps of the feathery Pampas Grass, which are rendered prominently effective by the dark background of foliage. Looking across the water the view is charming; while to the right is another object of notice—the noble cathedral of Lincoln crowning the hill, and in the line of vision is also the castle which William the Conqueror erected to overawe his subjects. The view to the left is also pleasing: the lake contracting and vanishing through a long straight avenue of Willows. This water avenue is highly ornamental, and is unquestionably one of the finest features of Hartsholme. Such are the views from the grounds, we will now glance at the grounds themselves.

They were laid out by the eminent landscape gardener Mr. Milner, and right well has he done his work. Hartsholme may be said to be entirely artificial, yet its treatment has been so bold and wide in its scope that art is made to appear as but the "handmaid of nature," and every clump, mound, terrace, and dell appear to have a purpose as natural and necessary accessories to the lake. The lake has evidently been the keynote of the artist, and he has used it dexterously and skilfully. The carrying-out of the designs has been a work of great magnitude. The foundation was a comparatively barren soil, and the fact was wisely recognised from the first and boldly grappled with. No tampering measures were adopted and leaving the rest to chance and hope, but a solid foundation was made; and not only were new trees brought but new soil was provided for them to grow in. And here lies the secret of the success of the wonderful growth which the trees have made—new soil. This was no mere sprinkling and mixing with the old, but thousands of loads of fresh soil were brought; and it is to the thoroughness with which this important work was carried out that the great success which has been attained must be primarily attributed.

On entering the grounds by the carriage drive we find inside the gates a substantial-built ornamental lodge. To the right is a fine clump of Hollies, consisting of the best varieties in cultivation of the Golden and Silver-leaved kinds, intermixed with Irish and common Yews and flowering shrubs. On the left in a sheltered recess is a specimen of *Wellingtonia gigantea* of symmetrical shape 80 feet high, and a fine group of *Cupressus Lawsoniana* 16 feet high, feathered to the ground and in exuberant health. There is no crowding of trees and shrubs to be found at Hartsholme, for all the commoner shrubs have been judiciously thinned, so that every plant is a perfect specimen. Approaching the Hall a large irregular-shaped bed of *Rhododendrons* is noticeable. It comprises numerous rare varieties; and when covered with rich masses of bloom in various colours from the deepest crimson to the most delicate white, many of the trusses measuring 24 inches in circumference, the effect is most beautiful and imposing.

On passing the front of the Hall we descend a flight of stone steps in front of the mansion, and notice a sunk panel or winter garden tastefully laid out and filled with dwarf-growing evergreens, consisting of *Rhododendron Wilsoni* edged with *Skimmia japonica* and dotted with dwarf varieties of the Golden-leaved Hollies, which help to light up the more sombre hues of the Ives and Yews. We next pass on to the dell, but at every step there is much to admire. On the left is a fine group of *Cedrus Deodara* 30 feet high and 20 in diameter; on the right is a noble specimen of *Wellingtonia gigantea* 30 feet high of symmetrical shape. We now enter the dell, which is a place of rich floral beauty difficult to describe. Banks of *Rhododendrons* meet the eye on every side. At the bottom of the dell is a small ornamental pond containing the white Water Lily surrounded by a carpet of grass, standing on which in the early summer we are as it were buried in a rich mass of gorgeous flowers sheltered on every side by tall trees. Noticeable here is *Abies Douglasii* 30 feet high with a spread of branches 16 feet, and *Thuja gigantea* 24 feet high. We next come to a specimen of *Cupressus Lawsoniana* 24 feet high of perfect shape, and the ever-to-be-admired Cedar of Lebanon.

We now come abruptly to a terrace walk 800 yards long by 12 wide. This terrace runs parallel with the Skellingthorpe road, which is completely masked by a bank of shrubs. On the opposite side is a line of Beech trees 30 feet apart, which promise in the course of a few years to make a very inviting shady promenade. The terrace runs along the margin of the lake, and is upheld by a substantial and ornamental brick wall with recesses at equal distances; these are planted with *Rhododendrons*. From this terrace the view is very beautiful: on

the left the mansion, on the right a well-wooded and park-like landscape, and in front the lake, with a bold island in the centre and a large fleet of black and white swans.

We now pass to the west side of the pleasure grounds, traversing a winding walk with many fine specimen shrubs on either side, terminating at the head of the lake. The flower garden proper is on the south side of the mansion. Although of limited dimensions it is exceedingly pretty when clothed in its summer attire. Formerly it had in its centre a circular bed elaborately embroidered with Box, which was considered the gem of the place. It is now, however, replaced by a beautifully designed terra cotta fountain (by Pulham of Broxbourne), surrounded by small flower beds. Another straight broad walk extends from this point about 150 yards long, with embankments on either side consisting of projecting mounds

and sheltered recesses. The banks are planted with a choice selection of shrubs; the recesses, which are about 20 yards apart, are planted alternately with Deodaras and Wellingtonias. At the extreme end of this walk is an ornamental Gothic summer house fitted up with coloured glass windows by Firman of Manchester. During the last six or seven years the trees and shrubs have made such rapid progress that it has been no light task for the gardener to keep abreast of the work of thinning and pruning. Many shrubs have had to be removed to make room for those left, but by perseverance and hard work all are now in admirable order, and no better kept shrubberies and pleasure grounds are to be found than those of Hartsholme; their extent is about twenty acres.

The kitchen garden is conveniently situated, crosses walks dividing it into four quarters with walks round the sides. The

Fig. 63.—HARTSHOLME HALL.

walls are covered with Apricots, Pears, Plums, and Cherries, which annually carry heavy crops of fruit. Pears, Plums, Apples, and Cherries are grown as espaliers by the sides of the principal walks trained to strong, strained, galvanised wire. Vegetables are also largely and well grown in outside quarters of the garden. Near to the mansion is erected a very fine range of glass 150 feet in length by 18 feet in width. This range is divided into four compartments, consisting of a conservatory and two vineries and orchard house. The houses are approached from the south terrace through a Gothic archway and a small alcove intended for a fernery. On the end wall of this alcove we noticed a fine plant of *Oytisus racemosa* covering a space 6 feet square and profusely clothed with yellow flowers. The *Heliotrope* is also employed as a wall plant, and choice varieties of perpetual-flowering Carnations 5 to 6 feet in height were covered with bloom. The white and crimson Glove, Mignonette, forced Roses, Lilies of the Valley, and other plants, are largely and well grown for the conservatory, which is occupied by a stage surrounded by a path with latticed tables on the sides. The next house is the early vinery. The Vines had evidently a robust constitution, and the Grapes from Hartsholme have gained a good local reputation. The next compartment is a late vinery, and from these two vineries alone excellent Grapes have been cut nine months out of the twelve. The sorts grown are Black Hamburgh, Muscat Hamburgh, Muscat of Alexandria, Lady Downe's

Seedling, Gros Guillaume, Foster's White Seedling, Mrs. Pince's Black Muscat, and Black Alicante. Mr. Allis finds that to bring out the true qualities of Alicante it must be grown in an early house, the Grapes keeping better after being cut than the same kind grown in a late house, besides the quality being much better. The Alicante is not keeping quite so plump this season owing to the cold and wet summer and the crop being somewhat heavy, while Lady Downe's which has smaller bunches are at this date (February 24th) fresh and plump; but in favourable seasons Alicante is the best late-keeper. Muscat of Alexandria and Bowwood Muscat have ripened and kept very well in a late house encouraged with a little fire heat and plenty of air in the ripening season. Bowwood Muscat is similar to Muscat of Alexandria, but a hardier constitution. The front walls of the vineries are built on arches, and the Vines planted inside with about 6 feet of border inside and about 14 feet wide outside on a gravelly subsoil. The outside borders have a good thick coating of farmyard manure early in the autumn sufficient to keep out frost. The gardener is of opinion that the rainfall has something to do with Grape-growing. In 1874 the total fall at Hartsholme was a little over 16 inches; in 1875 it was 22 inches and the Grapes better. He also thinks it is a mistake to keep Vine borders very dry at any season of the year where the subsoil is light.

At the extreme end of the range is an orchard house, but the trees are now planted out and heavier crops are produced

than when they were grown in pots. They are in excellent health. Contiguous to this range is a span-roof forcing house in which Cucumbers and Melons are grown; there are also the ordinary adjuncts of frames, &c.

Hartsholme is a beautiful garden and is well managed. For some years it was in the charge of Mr. Allis, who is appointed to a higher charge on another estate belonging to Mr. Shuttleworth. Mr. Allis is, I believe, to be succeeded by Mr. J. Holah, who is well known to be a skilled gardener. At Hartsholme he will have scope for his abilities, and both place and owner are worthy of his best services. Hartsholme is about two miles and a half from Lincoln.—J. W.

SOWING AUCUBA BERRIES.

I know of no place where the berry-bearing Aucubas succeed so well as here. There is one bush now so covered with fruit that about a week since I directed a man in the garden to tie up one of the branches, which seemed likely to break from the weight of berries upon it. It is astonishing how far the male plants spread their pollen. I think we have some plants with a good crop of fruit at the distance of 100 yards from the male plant. One of our plants is now about 7 feet high and of about the same width, with berries I might say almost equal in number to its leaves.

As to the sowing, we have merely placed the seeds in the soil in the kitchen garden, and with perfect success; and it may be useful to state that I have every reason to believe that the male and female plants raised from seeds ripened here flower at the same time. Though the bought male plants flower earlier, they are never with us too early to affect the old Aucuba shrubs which we have had for very many years.—W. W. E. WYNN, Penarth, Towyn Merioneth.

SOIL FOR RHODODENDRONS.

RHODODENDRONS do with me as well in a good Rose soil as in peat—in fact I think they do better. I can obtain plenty of black bog, which is equivalent, I suppose, to peat, but I find it unnecessary. The Rhododendrons here are all in the churchyard with standard Roses, and I find the two do wonderfully well together.

If anyone wishes to make a very effective border I should recommend him to have a background of Rhododendrons, and next half-standard Roses about 3 feet apart. Between each standard Rose plant *Lilium auratum*, and in the next line Chrysanthemums, and then Gladioli. He will have flowers then from May till November; and he can, if he likes, plant Hyacinths and other bulbs *ad libitum* in the autumn, provided he removes them in good time after flowering. I make use of this border in my churchyard, and it is only in the depth of winter that we are without flowers. I find Gladioli answer wonderfully well between standard Roses, and Mr. Kelway was astonished at the height that they grow here.

With regard to growing Roses in my churchyard a lady made a most delightful remark to me once at a Rose show. "Oh! Mr. Camm, I never will look at your Roses, for I hear they are grown in the churchyard; and that being so, I know from where the trees derive their nourishment, and I consider the idea most horrible." In vain did I assure her that the roots never went further than a foot into the ground, and that our object was to keep them as near to the surface as possible. She was as obstinate in her conviction as an old man once was in Sussex where I was curate, who never would eat mutton, for he was afraid of eating his grandmother, as the sheep grazed in the churchyard where she was buried.

Rosarians are anxiously looking out for the fixtures of the Crystal Palace and Alexandra Palace Rose Shows. It is now the beginning of March and they are not out. These London shows ought to be fixed at the earliest possible date, as country Rose shows must give way to them, and it is necessary to fix the day early so as to avoid clashing with other shows. Perhaps before these lines are in print we shall see the announcement of the dates in your columns.—JOHN B. M. CAMM.

I can endorse all that Mr. Luckhurst has said, and go to greater extremes than he has done. Here Rhododendrons grow well and flower abundantly in every kind of soil except sand. I never knew in any locality the soil to vary so much in a given area as it does in this neighbourhood. If I had to choose between peat and loam I would certainly prefer the latter, unless I could procure some better peat than we can

obtain for either love or money, not excluding the Surrey far-famed peat.

Here we have Rhododendrons growing and flowering most luxuriantly in a very stiff clay, which in a dry summer is so hard that it is almost impossible to get a spade into it; but where the clay is well drained the plants do well, but where the drainage is defective they only just live. Those in loam without a particle of peat grow too much, for we have to be constantly thinning them out or they would soon spoil each other. We have had peat from a neighbouring forest to plant some of them in, but those are best in the loam. I was removing some last week which had been planted sixteen or more years; where the peat had been put to them they were not nearly so well rooted as those in pure loam. Localities and the quality of the peat may have an influence upon them, but in this place and neighbourhood anyone can see the above facts for themselves.—D. WALKER, *The Gardens, Dunorlan, Tumbidge Wells.*

In the first paper on page 84 it was stated that "the planting of Rhododendrons was well and carefully done, and the rest was left to Nature." Let me commend this sentence to the attention of "J. B.," with a little more of my practice and its results.

I have repeatedly explained the importance of a careful preparation of the soil for all kinds of trees and shrubs, and to none does this apply more forcibly than the Rhododendron. Crowd its roots into a hard crude mass of soil and it will exist even for years, but it will make no appreciable progress. The growth, if any ensues, is hardly perceptible, the foliage becomes of a sickly yellow hue—the plant is in a state of utter stagnation. Break-up that soil, stirring it deeply among the plants, throwing it up roughly to the action of the air—you need not disturb the plants—and mark the result. Why, it is just as if a magician had waved his wand over the spot with a vivifying power that is absolutely marvellous. The foliage acquires the deep green tone of health, shoots and branches spring forth clothed with foliage that is gigantic in comparison to that upon the old and stunted growth, and a brief season or two brings to the scene its highest finish in the crowning glory of those lovely flower clusters for which this shrub stands unrivalled. This is no flight of fancy, but is a simple deduction from actual experience. Plant well if you plant at all, stir the soil deeply, trench it if possible, only give the plants a good start, and all will be well; but pray do not just stick in your plants and forget them. A little pains and care with the soil and plants in the first instance will ensure successful results; without them failure may, and in point of fact often does, ensue. We ought not then to lay blame upon the soil.

There is nothing equal to the logic of facts to enforce a truism. Here is an example for "J. B." Some three years ago two gentlemen purchased a few thousands of four-year seedling Rhododendrons, each having an equal number, and placing them in the hands of their respective gardeners, with a request that due attention and care should be given to their culture. What is the result? In one instance there is a fine stock of healthy bushy plants, most of which will be a couple of feet high by next planting season, and in the other every plant has failed. Now, peat has nothing to do with this success, for none was used. The plants were first put thickly into raised nursery beds of ordinary loam, watered, weeded, and transplanted in due course—all very ordinary and simple matters, but eminently necessary to success.

Turning now to what "J. B." has said about loam, he evidently thinks that its staple must be of the highest excellence—"beautiful sound yellow loam that makes a gardener's teeth water." I can assure him that the soil with which I have to deal is far more likely to affect the eyes than the teeth, for it is certainly the reverse of beautiful or sound. It is thin, and so miserably poor that no vegetables will grow in it in its virgin state. But then I have proved that the Rhododendron does not require a rich soil; at any rate, not rich in the ordinary acceptance of the term. Soils apparently poor evidently contain certain nutritious substances suitable to its requirements; and this opens up a very wide field for discussion as to the adaptability of certain plants to certain soils, leading to the conclusion that all soil contains nutritious matter if we can only discover the class of plants for which it is suitable. This matter is so important that I hope to revert to it more fully upon some future occasion.

By all means use peat if you have it. I have not the slightest objection to it, but do not let it prove a stumbling block

to you. Do not let the want of it hinder you from planting if you are not in a limestone district. And pray, "J.B.," do not suppose that I shall mislead in this matter. I have no reason to avoid using peat if it was really indispensable, for I have an unlimited supply at my disposal—fine natural beds, many acres in extent and of excellent quality. It might be asked with much propriety, Does the use of peat always ensure success? It does not. How frequently one meets with sickly clumps of *Rhododendrons* planted in peat! I have sometimes wondered what the proprietors of such miserable scrubs thought of the dogmatic sentences of the "peat or nothing" men—that is to say, if they ever took the trouble to think about it at all; not that I would infer that the peat is at fault—no, it is the planting. Again I say, Plant well if you plant at all. How can you suppose a shrub will thrive if you thrust its roots into a puddle of stagnant water? and that is precisely the case when peat is thrown into an excavation in a mass of clay or other tenacious matter holding water like a pond. It is just a death-trap, in which healthy roots cannot exist. Flowing water, or rather water that is percolating through the soil, is not fatal to the roots, for they revel in such soil. In circumstances of this nature I certainly prefer peat soils. For example, in planting a fringe of Alpine *Rhododendrons* around a fountain the soil used was turfy sods broken up roughly and broken bricks in equal parts, with a drain connected with the fountain waste. Thus, although the soil is constantly saturated with the fountain spray, yet there is no actual accumulation of water about the roots, and the condition of the plants is satisfactory in the highest degree.

When the *Rhododendron* assumes its legitimate position and becomes the shrub of all gardens it will quite supplant the Laurel, to which it is decidedly superior in beauty of foliage, to say nothing of the blossom. I could pick foliage of extraordinary size, and I am convinced it is not uncommon, for I have just received a trailing of a leaf measuring 11 inches long by nearly 5 inches wide, growing upon a plant in the nursery of Messrs. Casson, out on the moors, of Thorne near Doncaster.—EDWARD LUCKHURST.

PHALÆNOPSIS SCHILLERIANA.

THE following history and mode of culture of the fine plant which was exhibited by Mr. Bass, M.P., at South Kensington, and to which the medal was recommended to be given from the Davis fund, has been forwarded to us by Mr. Bennett, the skilful gardener at Bangemore.

"The plant was sent from India about three years since by Mrs. Plowden, a great enthusiast in horticulture, with a numerous collection of other Orchids. They were very badly packed, so much so that out of twenty-seven *Phalænopses* of sorts only six arrived with any life in them. The one in question had one leaf about 8 inches long quite shrivelled up, and two roots broken off. They arrived in that deplorable condition that, though worth a considerable sum in India, I sent word to Mr. Bass when the plants were unpacked that I thought they were worth about £20. Immediately upon unpacking I hung them on the back wall of a north house, against which I had first nailed some garden mats. These, from being regularly syringed, kept the plants moist.

"There were several blocks of mahogany wood sent over with them, and to one of these I wired the *Phalænopsis*; and as it began to root to it after being on the back wall for six weeks, I put the end of the block in an 11-inch pot, filling-up the pot and making the block fast in it with crooks and some lumps of Eppe's fibry peat, covering the top of the pot and the whole of the block with live sphagnum. The first season the plant sent up a weak flower spike; the second season the roots made great progress, running down the block and all among the crooks and peat, and the plant made two leaves 18 inches long and 5 wide, and in the spring threw up two flower spikes bearing one hundred flowers. The peat was then, as far as possible without disturbing the roots, picked out and fresh added, and last season the plant made two more leaves 1 foot long and 5 inches wide each, and showed two more spikes of bloom, but from the leaves not being quite so long this season as last, I decided on only leaving the one spike.

"The present spike is 5 feet long and 3 feet across, and the plant measures, including the spike, 6 feet 2 inches high. There are nearly eighty flowers on the spike. The block stands about 15 inches out of the pot, the plant being on the extreme end of it, and I cannot help thinking that the position of the plant has something to do with its success, as I have several

in the same house under the same treatment as regards water and temperature, only some of them are in pots and the others in baskets, none on blocks in pots; these are all doing well, but nothing extraordinary. I shall grow them on blocks for the future.

"The temperature has been for the months in autumn and winter from 60° to 65° at night with a rise of 5° by day, the summer temperature 70° to 75° at night with a rise by day, with plenty of moisture; the plant has been well watered, and shaded from the sun. I cannot too strongly recommend Eppe's peat for Orchids; I have found it as fresh when re-potting as when first used."

[Barely, if ever, has this beautiful Orchid been exhibited with a finer spike than the one referred to, and we are glad to find that Mr. Bass's valuable plant received no injury by its long journey, which is encouraging to others contemplating the exhibition of commendable specimens.—Eds.]

ROAD-MAKING.—No. 3.

HAVING provided for the foundation we now come to what may be called the finishing material, and here I expect to be met with the usual remark, "The product of the neighbourhood is all we have to employ." This is doubtless true in many cases, but not in all; and even where there is no choice the mode of using such materials has much to do with the cost of the road as well as its quality, for to empty cartload after cartload upon ground plunged-up with wheel-ruts and other unevenness, without any attempt at leveling, is downright waste. Where the work has to be done in wet weather the carting ought always to be done upon the road that is made, and it is better not to take either horses or carts upon the soft ground on which the stones have to be laid; and if it be very soft a slight covering of heath or branches—even hedge clippings or rubbish of any kind—will save a great many stones being lost in the clay or mud. As to the material, I have no hesitation in giving the preference to broken stone over sifted rounded gravel. Although the latter often makes a good hard road, it is some time before it sets well, especially in hilly roads; so that where it is possible it is better to have at least a portion of broken stone to mix with the gravelly pebbles.

It has often been a question amongst those most interested in the well-being of our roads, whether the somewhat hasty abandonment of the old-fashioned pavement or causeway which took place about a century ago, was not in many cases an injudicious one. Certainly the rage for macadamised roads, as they are called, has received a check since then, and the pavement in some streets, &c., that was pulled up to make way for this so-called improvement has been laid down again. Good paved parish roads are yet to be met with in Cheshire and Lancashire, and not very many years ago one of the turnpike roads leading out of Bolton had rather a peculiar appearance, one-half of it being paved and the other half macadamised, a sort of a kerb to the paved portion running-up the middle of the road, and I believe the latter was most used in winter, while the other was the summer favourite. But paved roads of a common kind are often made of a soft stone where a hard one is not to be had, and it answers much better in this form than if it was broken-up, besides which a paved road is much easier kept clean in dirty weather; and it would be well for those interested in such matters to give some further trial to the pavement before they too hastily condemn it, for notwithstanding the perfection to which macadamised roads have been brought they are costly, and in spite of the comfort which the steam roller has given to the pedestrian crossing a street that is newly covered with fresh stones, it is vexing to find how soon the operation has to be repeated. In the formation of new places the value of paving should always be considered, for it is particularly suitable for many positions, and especially by the sides of buildings and where special work has to be done needing a smooth hard surface.

Roads ought not to be made too high in the centre, as by that means the traffic is too much confined to the middle, but a little roundness is necessary to throw the water to the sides. Where the traffic can be controlled at the beginning it is much better for it not to be always in the same route. A hint this way from someone in authority will do much to more speedily render the road a good one all over instead of in one or more tracks. A rolling with a heavy roller will do good after rain, especially if done early enough in the winter for the road to become consolidated before dry weather sets in.

We would not advise that any finer gravel be put on until then, as it is so likely to be worked down to the bottom; but if it be late and dry weather imminent, a scattering of finer material may be made on the top, or sometimes finely broken stones can be had which do equally well. Chalk is sometimes used, but it is so liable to render a road impervious to rain that we would rather adopt something else, but it may be used rather than that loose stones should roll about all the summer. I will conclude by again urging the propriety of not begrudging the spade-and-mattock work at the beginning, which after all is half the battle in the formation of a road, and the ease and comfort it gives in travelling afterwards.—JOHN ROBSON.

BEEBLE EATING IRIS.

In the page 180 to correspondents Mr. W. asks what proof I have of *Carabus hortensis* having eaten *Iris reticulata*. The plant was under a glass in a pot. It was eaten down, and the beetle found on it. The gardener told me that on squeezing it a quantity of green stuff came out, just as from a caterpillar: this can hardly have been anything else than the remains of the unfortunate plant; and the only way I see of escaping the conclusion is by supposing, without evidence, that something else devoured the Iris, and that this something was devoured by our beetle.—G. S.

EPIPHYLLUMS.

At page 192 of vol. viii. New Series of this journal is an article from my pen on these very desirable plants; in that, as in the present instance, in reply to a correspondent. Since then twenty volumes have been issued and half as many years passed, during which it is anticipated there are many new subscribers to whom it would be useless referring to the paper in question; therefore I may, without prejudice to what has been previously advanced, now report progress, convinced that a decade of experience the most advanced in horticultural art will have effected considerable improvement on former practice; for let no one think they are upon the threshold of an horticultural millennium, rendering continued efforts futile.

Epiphyllums are numerous, there being a dozen and a half or more of varieties of *E. truncatum*, all more or less distinct in contour and of colour of flower, sufficient to render appreciable a distinctness in varieties which in species would not be admitted. There is also a difference in the time of flowering of the several varieties. The plants are grown in two ways—namely, on their own roots, and grafted on *Pereskia* stocks. On their own roots they do not attain to anything like the dimensions of grafted plants, though this mode of culture affords very useful plants for facing and filling-in where taller plants would not be admissible, and they possess an advantage over grafted plants in taking up less room, small pots only being required.

Cuttings strike freely, kept for a few days on a shelf for the wound to dry before insertion in light sandy soil. The cuttings may be of any size, from the simple shoot of 3 or 4 inches in length to that of a branch with several armbuds and many shoots, and inserted no deeper in the soil than is sufficient from the pressure of that against the cutting to prevent its falling over; or a small stick thrust alongside the cutting, if large, will maintain its equilibrium. The cuttings should be taken off immediately beneath a joint, the joint of severance being secured for the cutting. When the plants have been kept over-wet during the period of rest and the roots have decayed, or injury by any other means has prevented the plants deriving support from the roots not increasing in size, aerial rootlets are formed sufficient in most cases to maintain the plant (if the atmosphere be humid) for some years, leading to the inevitable conclusion of the plant's epiphyllal nature. I have further noticed that if moss be placed around the shoots at a joint—no matter how thick it may be—and secured with a ligature of matting, that roots will be emitted if the moss be kept moist, and the shoot or branch being detached and potted will grow away freely if placed in a brisk moist heat. Cuttings, however, root so readily that there is no need of a preparatory process.

Cuttings should be inserted in spring in light open soil in a brisk heat, keeping moist but avoiding watering more than to keep the soil in a moderately moist state, the cuttings being inserted around the sides of the pots, and when rooted potted-off singly in 8-inch pots. If the plants have filled the pots with

roots, and have made, or are making, good top growth, shift into 4½-inch pots in May or June, and by the end of July or early in August the growth will be complete. They should then have a lessened supply of water, and the sprinkling overhead be discontinued, and have a light and airy position. A warm greenhouse or cool stove—an intermediate house, in fact—gives the most suitable temperature, but the plants may be grown very well by those having in addition to a greenhouse a vinery started in February or March, which from the moisture and heat will conduce to a vigorous growth, that being completed by the time the Grapes are ripening, when the plants may be removed to a light airy position in the greenhouse with water only to keep the growths plump.

The plants if kept in an intermediate house will commence flowering in November and continue until February. When the plants have ceased blooming water should be withheld (the plants having after the flowers appear been kept moist), but not so as to cause the growth to shrivel. If they have a month to six weeks of this rest after flowering the plants subsequently grow much more vigorously, and especially if the growth is kept from being made until the days are lengthened. Any pruning required should be done when the flowering is over and the plants are kept dry. It may be practised advantageously when the growths are very close, and to give symmetry by the reducing of irregular growths. It may be done by breaking off the shoots at a joint, the plants appearing to grow all the better for a good thinning of the shoots.

When growth commences the plants should be repotted, taking away as much of the old soil as possible without injuring the roots, and they may be returned to the same pots, adding fresh soil. The most suitable compost is light turfy loam, very fibrous and chopped up moderately small, with an addition, in equal proportions, of dry cow dung, sharp or river sand, and crocks—or what is better, soft bricks broken into small pieces. The potting should be moderately firm and the drainage thorough. At one time I thought fibrous peat should form a part of the compost, but I do not now employ it for these plants, they making a more vigorous growth in that at present employed.

When the plants are in free growth and the roots active liquid manure may be given abundantly; a peck of cow dung to twenty gallons of water answers well, or one peck of sheep droppings to thirty gallons of water, one peck of soot to thirty gallons, or one pound of guano to twenty gallons of water, avoiding making the soil sodden, and leaving off the applications of manure water when the growth is complete.

Although the plants may be grown in a vinery where they must necessarily have shade, yet I find shade is not necessary even during growth, the plants without it growing more strongly, and have much better substance and larger blooms. Afford them light, therefore, if possible during growth, and free ventilation with abundant atmospheric moisture, sprinkling or syringing twice daily (morning and afternoon), and a temperature of 60° to 65° at night, 75° to 85° or 90° with sun and air by day. When the growth is complete 50° to 55° night, 60° to 65° day, to 75° with sun will be suitable; and afford water at that time to maintain the growths plump, for over-dryness is prejudicial to these plants, though not perhaps so injurious as extreme moisture.

Useful and attractive as are plants on their own roots, those grafted on the *Pereskia* stock (*Pereskia aculeata*) are infinitely superior both in vigour of plants and their ornamental character. The stocks are readily obtained by inserting cuttings any time during summer, but the present is perhaps as good a time as any, as the *Pereskia* now starts into growth. Cuttings of about 6 inches in length, which may be of the growing points or the shoots cut into lengths, inserted singly in 3-inch pots in light sandy loam and plunged in a bottom heat of 75° with the soil just moist, will soon have roots showing at the sides of the pot. The cuttings, it may as well be said, will strike freely during summer in a vinery or other place where there is a brisk moist heat; and when they are established we shift into 5-inch pots and encourage growth by affording bottom heat and plenty of moisture, the shoots being supported by stakes as they advance in growth, the plants being taken up with a single shoot; and when they have attained a thickness for grafting equal to that of the scions the operation may be performed, selecting for scions the roundest shoots and such as are likely to branch equally. The stocks should be kept rather drier and withdrawn from the hotbed, if in one, allowing about a month or six weeks to become ripened, and then they are ready for grafting.

For table plants short standards are best about 15 inches high, and the usual mode of working these is by wedge-grafting. A cleft is made in the stock at the top and about an inch long to receive the scion, which is cut like a wedge and must fit exactly. This mode of grafting is illustrated and described in the "Cottage Gardener's Dictionary," page 891, and "Science and Practice of Gardening," page 246. The graft being secured by thrusting through the stock and scion a spine of the *Pereeskia*, binding lightly with cotton so as to keep the edges close, and grafting wax may be placed over it to exclude moisture and air; or it answers equally well to bind a little more over the union and keep it moist with the syringe, the plants being kept rather close and moist until the union is complete, as it will be in three weeks or a month, or it may be longer, as the plants are in a medium for effecting a speedy growth.

In the case of pyramids the stocks will require to be taller and stronger than those required for table decoration; they should therefore, when the 5-inch pots are filled with roots, be transferred to 9-inch pots, continuing the moisture and bottom heat until they are sufficiently strong for grafting. If extra tall plants are wanted the stocks may be cut down to 9 inches, and kept rather dry until they break, when they should be shook out, returned to the same pots, and have brisk top and bottom heat, with abundant moisture, selecting the strongest shoot and securing it to a stake, removing the others, and shifting into 9-inch pots when the 5-inch pots are filled with roots. These plants are dried a little when of the size required for grafting to induce ripening, and are grafted, commencing at about 9 inches from the rim of the pot, and at that distance upward on opposite sides of the stock, the top of the stock being grafted as for dwarf standards, the only difference between it and those on the sides being their insertion on the side of the stock instead of on the top, a sloping incision being made with a sharp knife extending down the stock an inch, a scion being selected of the same diameter as the stock, and prepared wedge-like to fit exactly the incision in the stock, into which it is inserted, secured with a spine of the *Pereeskia* passing from the front through the stock and scion, securing as before stated with a little moss tied over the union, and kept damp by frequent sprinkling of water from a syringe. A moist and rather close atmosphere facilitates the operation.

Standards may be had of almost any height, but for general usefulness the low standard is best. In the case of standards 18 inches high for table purposes a scion may be put on the top and two others about 6 inches lower down on the sides of the stock, which of course form a head sooner than one scion; whilst for tall standards one on the top and two 9 inches down on opposite sides of the stock, but with some little distance higher or lower in each case, so that they may not be upon the same plane, for that would be to cut the stock through.

It will be found that the stem will not be able to support of itself the succulent put upon it, and wood stakes are certain to break off at the surface from decay, and for tall plants do not maintain the plants erect. Iron stakes with three or four prongs fitting within the rim of the pots are most suitable, and should be painted green. Even these, after the plants become well furnished with spray, are not certain to maintain the equilibrium of the heads. I have seen a wire run round the pot beneath the rim, and from this copper wire taken to the centre stake, securing to it and the wire round the pot under the rim, and three or four of those equidistant around the pot prevent the displacement of the head from the perpendicular. It is also well to secure the stock and the scion to the upright stake with copper wire, or lead answers when the growths are moderate.

The plants will hardly need potting the year of grafting, but the following spring the potting should be liberal, giving a plant from a 9-inch pot a 13-inch or 15-inch pot, watering carefully until the roots are in possession of the fresh soil, then watering copiously, and when full of roots with liquid manure. In future years the pots may be increased in size, but not so much as in the first, and after the second year the surface soil may be removed, and a top-dressing given of equal parts of turfy loam and cowdung, potting only in alternate years.

Well-grown plants of *Epiphyllums* are splendid objects, and the flowers are of the finest for cutting—G. ARBER.

AGE WHEN SEEDS CEASE TO GERMINATE.—Peas and Beans will germinate, I know, after three years, and Parsnips when

two years old. I have Melon seed saved in 1857 in first-rate condition, and Cucumber seeds of 1861. I think it mostly depends in the place where they are stored.—L. ARTHUR BRENNAN, Clerk, Cloughban, Pomeroy.

DO RABBITS EAT LILIUMS?

Now that these beautiful flowers—I mean *Lilium auratum* and the different varieties of *L. lancifolium*—are being freely planted in shrubberies, a question of considerable importance is raised as to the danger of the young shoots being devoured by rabbits. I have recently made private inquiries on the point, and the information I have received is somewhat conflicting, the purport of it being that rabbits will eat the shoots of some kinds of *Liliums* leaving others untouched, and that *L. auratum* generally escapes injury. If cultivators of *Liliums* in rabbit-infested districts would communicate their experience on this matter, naming those sorts which rabbits injure and those which they do not molest, the information could not fail to be valuable and opportune.—J. W. B.

[We have other inquiries on this subject, and we should be glad to receive the experience which our correspondents are seeking.—Eds.]

NOTES AND GLEANINGS.

CLEVELAND HOUSE, Clapham Park, Mr. S. Ballie's small but well-managed garden, is celebrated for the high character of its summer carpet bedding. Equally good practice is to be found in the winter, the plants both in the stove and greenhouse evincing marks of high culture. In the former structure the Palms, Crotons, Orchids, &c., are, if not large, in superb health. In the greenhouse the beautiful and elegant *Boronia pinnata* is in fine condition; *Chorosema Chandlerii*, a plant two years old in a 10-inch pot, covers a 4-feet globe trellis, and is a perfect mass of flowers; *Primulas* are 20 inches in height and more than a foot through, perfect pyramids of bloom, and *Epacris* are admirably cultivated. Mr. Legg promises also to add to his fame as a cultivator a creditable position as a hybridiser, as he has not only succeeded in effecting crosses between the best of the Crotons, but has already raised a batch of seedlings which must be looked forward to with the greatest interest, as, considering their parentage, they cannot fail to prove varieties of distinct character and great merit. The seedlings show great dissimilarity even in their cotyledons, some of which are striped and mottled, which is a tolerably safe index of the brighter colours to follow. When we note that these seedlings are the result of intercrossing such fine sorts as *C. Weismannii*, *C. undulatum*, *C. majesticum*, and even *C. volutum*, it will be at once admitted that Mr. Legg has obtained plants of which he may be considered fortunate to possess. It is not chance, however, but well-applied skill that has produced this unusual and highly promising batch of seedlings, and Mr. Legg has our congratulations.

—We have received from Mr. George Lee, Clevedon, a box of blooms of his new VIOLET PRINCE CONSORT. We have seen and grown other improved Violets which have been introduced by Mr. Lee, but never have we seen flowers in any material degree approaching the remarkable blooms now before us. We think their colour is deeper and richer than in other varieties, and they are undoubtedly superior in size, and especially in the remarkable substance of their petals, to any examples of this flower which have hitherto come under our notice. Many of the flowers exceed $1\frac{1}{2}$ inch in diameter, and they are supported on stout stems 5 inches in length. This is a princely Violet, worthy of the name it bears, and will sustain the reputation of its raiser.

—M. ADOLPHE BRONGNIART, the distinguished French botanist, died in Paris on February 19th. He was born in 1801. Besides his many botanical works, Brongniart is known as one of the first to discover the pollen-tube and the important nature of the offices performed by it in the fertilisation of plants.

—THE noble tree (for such it really is) of *BROWNEA GRANDIOPES* that some weeks since gave promise of a more than ordinarily fine bloom in Glasnevin Gardens, Dublin, has fully realised our anticipations, having up to this time developed some three dozen or more of its huge compound brilliant flower heads, each as large as a child's. In some instances two are borne on the extremity of the same branchlet, weighing it down with a duplex mass of floral wealth weighing little short

of a stone. The more brilliant-coloured but less striking *B. grandiflora* in the same house is also producing a long succession of its showy and highly-coloured pendulous flower heads.—(*Irish Farmers' Gazette*.)

—MR. LUCKHURST has recently directed attention to the fact that *Rhododendrons* may be cultivated in any soil which is not of a limestone nature, and that peat is not a *sine qua non* for these fine evergreens. A conclusive example of *Rhododendrons* growing in loam is afforded in the beautiful grounds of Mrs. Hope at Deepdene, where they grow in the wildest luxuriance, and are driving common Laurels out of the grounds. At Deepdene there are many acres of these evergreens, and thousands of self-sown seedlings form in places an almost impenetrable thicket. The soil is sandy loam, and the vigour of the acres—almost miles—of *Rhododendrons* is remarkable.

—THE second meeting of the WIMBLEDON GARDENERS' SOCIETY was held on the evening of the 1st inst., and it must have been very gratifying to the promoters to find so large an attendance, sixty-six members and friends being present. The chair was taken by Mr. J. Ollerhead, the originator of the Society, who announced that the prospects of the Society were very encouraging. The result of the appeal to the gentry of the neighbourhood and others had been so far successful that a sum of about £40 had been given in money, and several gentlemen had made contributions of useful books. A discussion on the "Fallacies of Fruit Culture" concluded the meeting.

—WE have received from Henry Webb, Esq., of Redstone Manor House, Redhill, a truss of bloom of *CHINESE PARNASSIA*, in which the corolla is perfectly green, and the large inflated calyx is as long as the corolla. It is a singular-looking plant.

—FOR affording dazzling spikes of out bloom during the dark months of the year few plants are superior to *ALONSOA WARSZEWICZII*. We have lately seen a very fine form of this plant cultivated at Denbies. The flowers are of the richest velvety scarlet, and are produced in great profusion. The plant is of the easiest culture, few plants striking more freely and requiring less skill in culture. Mr. Beesley has great demands for cut flowers, and this is one of his favourite winter plants, the colour of the flowers being unusually bright and continue fresh for a long time in a cut state. The plants are grown in a light place in a warm greenhouse.

—THE following modes of making RUST CEMENT for water and steam pipes have been recommended by the "Engineer." Make a stiff paste with two parts sal-ammoniac, thirty-five parts iron borings, one part sulphur and water, and drive it into the joint with a chisel; or, to two parts of sal-ammoniac and one part of flowers of sulphur add sixty parts of iron chips, and mix the whole with water to which one-sixth part vinegar or a little sulphuric acid is added. Another cement is made by mixing one hundred parts of bright iron filings or fine chips or borings with one part powdered sal-ammoniac, and moistening with urine; when thus prepared, force it into the joint. It will prove serviceable under the action of fire. All the above parts are by weight.

COCKNEY CATERPILLARS.

A FINE illustrative chapter on the subject of "perseverance under difficulties" might be taken from the experience of many London amateur gardeners who work early and late at their small garden plots in spite of failures and disappointments. Just now as one goes through the suburbs one may see them digging and clearing the ground with a hearty determination to make the best of it, which is really encouraging, as showing how deep down in humanity lies the love of flowers. Even the poor apologies for flowers that are coaxed into spasmodic life in the smokier foggy districts are the sources of pleasure to men, women, and children; their very weakness in some instances increases the owner's affection for them.

Caterpillars are apt to prove a sore trial to the cultivators of the small suburban front and back gardens. The circumstance is open to a variety of explanations, but it is beyond denial that gardens near London, say within a distance of five or six miles from its centre, are much more pestered in this way than are gardens elsewhere. It may be that in some species, as is known to be the case with certain quadrupeds and birds, there exists a natural liking for the habitations of

man, which draws them about such a buzzing hive of humanity as is London. Or, again, it may be argued that these particular species thrive better in the warmer temperature near a great city than they do in the open country. I believe there is much in the fact that caterpillars near London concentrate themselves more, owing to the limited area in some districts, and also several species which multiply rapidly do in the suburbs confine their attacks to garden plants which, under other circumstances, would consume a greater variety of vegetable food. Take the familiar caterpillar of the Gooseberry moth as example. The caterpillar of this is, I think, nowhere such a pest to Gooseberry and Currant bushes as it is in suburban gardens. And why? Because in the country the moths fly hither and thither, depositing their eggs in a number of shrubs or trees growing in the woods and along the hedges. You may pick the caterpillars of *Abraxas grossulariata* off Oak, Hazel, Sloe, and Willow, and necessarily the gardens in the vicinity come off lightly.

Just however to reckon up the species that deserve especially to be styled "cockney" by their swarming in the neighbourhood of London, I note first the caterpillars of the common white butterflies, *Pieris* *Brassicae* and *Rape*. Not a patch of Cabbages can be planted which does not entice the settlement of one or other of these butterflies upon it; for the two species, I think *P. Rape* appears most numerous. They attack, of course, other *Brassicaceae* or *Cruciferous* plants, *P. Brassicae* frequently making havoc in beds of the *Nasturtium*. These alone of all the British butterflies feed up close to London, though stragglers of various species occasionally fly along London streets and roads. The Currant Clearwing (*Seisia tipuliformis*) comes on our list, for its caterpillar busily mines the Currant bushes in our western suburbs, and its large relatives, the Leopard Moth and the Goat (*Zeuzera Aesculi* and *Cossus ligniperda*) destroy branches and even trees in the London parks and squares. The brother Ermine Moths, *Arctia Menestri* and *lubripeda*, sneak about suburban gardens, the latter being rather the commoner. Both, from their hairy garb, enjoy the epithet, "Woolly Bear," applied indiscriminately to caterpillars thus clothed, and both are hearty eaters. *A. lubripeda* is remarkable for its habit when journeying of suddenly pausing as if to reflect, and then rushing on at a tremendous rate, so that few caterpillars could race with it successfully. The smaller and more variegated caterpillar of the Vapourer Moth (*Orgyia antiqua*) feeds on almost everything in the garden; it is presumed to be the only species of the order that still holds ground in the heart of London, feeding on Elms and Limes in melancholy city churchyards.

The Gooseberry Moth I have mentioned, and I next name the large "Looper" caterpillar of the Brindled Beauty (*Biston hirtaria*), far from beautiful in the eyes of gardeners, since it feeds not only on Elm and Lime, but also on Plum and Pear trees. The moths may be picked by dozens off the bark of trees in April, and the caterpillars leave tokens of their presence on the pavements whenever they happen to be located in trees near the footway, the "frass" that falls leaving a deep stain on the stones. A similar effect is produced by the feeding of the caterpillars of the Buff-tip (*Phalera Bucephala*) abundant in like circumstances, only these caterpillars rarely meddle with fruit trees. The dingy moth known by the inaccurate name of the Willow Beauty (*Boarmia perfumaria*), which some one suggested should be called the "Marylebone Moth," because it was many years ago apparently commoner in that district of London than anywhere else, sits visible enough on walls during the day, though the caterpillar, an Ivy-eater, is retired in its habits and seldom seen.

The ubiquitous Winter Moth (*Cheimatobia brumata*) conspires with the smaller and more lovely little Ermine (*Hyponomeuta padella*) to strip the foliage off the Hawthorns that grow in the neighbourhood of London; the caterpillar of the former species being by choice solitary and spinning its web unaided, that of the latter uniting with its brethren to form a social web. In some counties *C. brumata* has greatly infested Apple and Pear trees, which I have not observed near London, though several of my friends have shown me trees woefully disfigured by *H. padella*. The slim "Looper" caterpillar of the Garden Carpet (*Melantheria fluctuata*), a caterpillar which appears in a variety of colours, feeds chiefly on low plants in gardens, and does double mischief from the fact that it is double-brooded. The moth may be noticed flying about all the summer, even in the daytime. Rather general in its tastes is the hairy, one-humped caterpillar of the Grey Dagger Moth (*Acronycta Psi*), which may be observed feeding on

trees and shrubs about London till the leaves are nearly gone. This might do some mischief were it not that every season a good proportion of the brood is killed by the attacks of parasitic foes.

Amongst the smooth-bodied caterpillars of the Noctua division are some that evidently delight in a London life, such as that of the variable Cabbage Moth (*Mamestra Brassicae*), more especially troublesome in the kitchen garden; the Dot (*M. Pernicaria*), which prefers the flower beds and shrubberies; the Garden Dart (*Agrotis nigricans*); and the Great Yellow Underwing (*Trypocena pronuba*). The Gothic (*Noctia typica*) is plentiful in some years, scarce in others, the caterpillar having the peculiar habit of preferring trees or shrubs in autumn, and low-growing plants after its hibernation. Add to these the caterpillar of the showy Silver Y (*Plusia Gamma*), fond of an excursion in the sunshine, and that of the sluggish Anglehades (*Phlogophora meticulosa*), a caterpillar, however, less common in gardens than formerly, and we have a pretty formidable list of possible enemies from one order of insects alone, which vex the soul of the suburban amateur; and this is, moreover, one in which are not specified sundry smaller species of the Tortrix and Tinea sort, which are also capable of much mischief.—J. R. S. C.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

THE work in this department is well forward, there being but little to do except the sowing and planting of successional crops. When the quarters are dug or trenched during the winter all that is required at the time of cropping is to fork over the ground lightly; and if this is done on a fine drying day the seeds can be sown immediately after.

We have again planted Windsor Beans. This is the only variety used in the kitchen here; and although it is not so prolific as the long-podded sorts it is much better for the table. Those who intend to grow for exhibition will find the Seville Long Pod to be the best. We have made a sowing of this with the Windsor for comparison.

Another sowing of Peas has been made. We have already named the most desirable sorts to sow, but with many it is much a matter of taste, Laxton's Fillbasket being by some preferred to the Wrinkled Marrows. When a blue Pea is intended to be sown, not a Marrow, there is at present nothing equal to Fillbasket. It is of moderate growth, and bears an enormous crop of very fine pods. Standard, another of Mr. Laxton's cross-breeds, is said to be quite as prolific as Fillbasket but is a Wrinkled Marrow; this sort will be tried against the best of the old Marrows this season. The earliest crop is making rapid progress; the rows will in a few days require to have sticks placed to them. It is an advantage to place short sprays first at this season, and when the young Peas have gained the top of them to place the usual sticks. If the long sticks are put in at once they shade the Peas very much and retard them.

It is a good time to plant Globe Artichokes; there are several varieties, and it is as well to obtain a good selection at the first; the large Globe is the best. This is a vegetable which if it is planted on good deeply trenched ground gives but little trouble afterwards. The heads are also very useful for showing in a collection of vegetables in the month of June. The plants are usually surrounded with littery manure during winter; the rougher portion of it is now removed and the remainder dug-in. During this operation offsets or suckers may be obtained for planting-out. The plants should be grown 4 feet apart in the rows and 8 feet from plant to plant. Jerusalem Artichokes are generally planted in some out-of-the-way corner, but where this vegetable is esteemed a plot of good ground should be chosen; it should be deeply dug and well manured. The rows should be 3 feet 6 inches apart and the sets a foot apart.

Parsley may now be sown. A row at the back of a fruit border or as an edging to some of the kitchen-garden quarters is a good position for it. Spinach we generally sow between the rows of Peas; the round-seeded sort is the best for this season.

Brussels Sprouts and Savoys are important crops. We have very great difficulty to get either of them to grow through the season free from the attacks of the maggot that causes club roots. Some persons have recommended to replant frequently when the plants are young; but we never had the Sprouts better than they have been this season, and the plants were sown in drills and thinned out to the required distance without having been transplanted from the seed bed. It is too early to sow Savoys yet unless they are wanted for the end of August and through September. April will be early enough to sow for the winter supply.

About the end of April is early enough to sow the general crop of Beet, but a sowing may be made at once if it is required early.

The ground should be in good condition, and if possible dry at the time of sowing for this crop. Leeks should be sown at once if it is intended that they should grow to a large size, nor should the ground on which it is intended to plant them have been cropped previously. A small patch may be sown in a sheltered position, yet in one pretty fully exposed to light and air. The Leek is a gross feeder, and delights in plenty of rich moist manure. Sow a little Chervil seed on a sheltered border. Basil had better be sown in pots, and the pots be plunged in a slight hotbed. When the plants are large enough to prick-out, they should again be planted in pots to be put out in the open ground in a small bed of light soil in May. Attention must be given to sow small salads, such as Mustard, Cress, Radish, &c., almost weekly if a large supply is required. Thyme, Mint, and what are usually called pot-herbs that are perennial should now be planted-out. Most of them are propagated by division of the roots. We have planted-out Cauliflower plants that have been sheltered in a cold frame during the winter. The seeds sown on a hotbed will succeed them.

PINERIES.

Our fruiting and succession houses are still so full of plants that we have not had an opportunity to report the suckers that were put in some time in August last year. To have large plants for fruiting very early in 1877 their potting should now be done. The Pine is a very easily-grown plant, indeed there is very little trouble to grow the plants to a large size; but this is not exactly the object cultivators have in view. Moderately strong plants generally give the largest fruit. If the loam used is of a light sandy nature the plants grow to the largest size, and the whole mass of mould in the pots is thoroughly matted with roots before the fruit throws up, and is in such an exhausted condition that the pips seldom swell to a good size. This is not the case when the loam is of a heavy clayey nature. The top spit cut not more than 8 inches deep from an old pasture contains much fibre, which will keep the compost open even if it does contain much clay. When the loam has been rather heavy we have used a little leaf mould with it, and one part of decayed stable manure to five of the loam. Bone dust is also well adapted for mixing with the soil. The compost must also be rammed-in firmly. A loose potting material causes the plant to shake about in the pot, and if it is loose at the neck it seldom gives good fruit. At present the temperature can be kept up to 75° at night if it is desirable to hurry on the fruit for a purpose, though the fruit produced in a temperature of from 65° to 70° will be of better flavour, and will not be likely to have overgrown crowns.

VINES IN POTS.

We do not grow Vines for fruiting in pots now that the houses are in full bearing, but a few pot Vines are of great value to those who have young Vines planted and which are not yet in a bearing state. There is no difficulty whatever in growing fruiting canes the first season from eyes put in from the middle of January to the middle of February. It is best to put in the eyes singly in small pots. They will soon start in a little bottom heat, and when the roots have reached the sides of the pots shift them into larger pots. It is quite necessary that they be grown on without any check. By August the Vines will be in their fruiting pots; the strongest in 18-inch, and those of more moderate growth in 11-inch pots.

Figs in pots are now making rapid growth. They require to be freely syringed and supplied with plenty of water at the roots without overdoing it. Red spider attacks the leaves, causing them to become yellow. The water ought to be syringed on to the under sides of the leaves.

Orchard-house trees are now rapidly approaching the blooming period. We are careful to keep the soil in the pots of Peach and Nectarine trees sufficiently moist, but the roots must become pretty dry before they receive water. The house has been fumigated with tobacco smoke to destroy any aphid that may be upon the trees. Pear and Plum trees have not yet been removed into the house; they will be taken in as soon as possible. The flower buds are far advanced.

FLOWER GARDEN.

The borders are now becoming gay with spring flowers. Snow-drops and Crocuses are fading, but Primroses, Cowslips, Polyanthus, and the more refined Auriculas will take their place. Iris reticulata is also very beautiful, and the different species and varieties of Hepatica are now in full beauty. *H. angulosa* is an excellent species, but the plants have evidently been raised from seeds, as there is considerable variation amongst them. Some are very pale blue with small flowers, others have brighter-coloured flowers as large as a half-crown. Scillas are also in flower. These charming deep blue flowers are always attractive; but the brightest jewels may be spoiled by being badly set, so our lovely spring flowers show to the best advantage when the borders, walks, and lawn are kept neat and clean. The wet weather has caused the worms to work on the lawn. To crush the casts down a heavy roller has been run over it, and in a few days the lawn-mowers will also be brought out. The grass is coming uneven, as it generally does until after the first mowing. Auriculas in frames are throwing up strong trusser. We look

over the plants about once a-week to remove mouldy leaves, and as yet the plants do not require water oftener than this. The frames are aired pretty freely, but the plants are not exposed to high winds.

Carnations and Picotees have not made much spring growth as yet. The frames are aired even more freely than the Auriculas; in fine weather the lights are removed altogether. The potting material has been made ready. The loam was mixed with half-rotted manure two months ago; to this has now been added leaf mould and sand; river sand is the best. The plants will be potted as time permits. The end of March or even early in April is time enough. The best growers pot two plants in a 10-inch pot. The object of using pots this size is not altogether for the sake of producing large flowers, but to have plenty of room to layer the grass when the blooming period is over. It is quite as well to place the pots back into cold frames after repotting; but if this cannot be done, and it is necessary to place them out of doors, we would then rather delay the potting until the first or even the second week in April. The hoe has been run through Pink beds to loosen the soil, so that atmospheric influences may have more effect upon it.

Bedding plants are now being potted-off from the cutting pots. Some of them have been planted in shallow boxes. Zonal Pelargoniums and others of a similar hardy nature are still in heated pits or late vineries; they will very soon be placed out of doors in turf pits and be sheltered from frosts by canvas shading.—J. DOUGLAS.

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

BRISTOL (Spring Show). March 22nd and 23rd. Mr. G. Webley, Holm Wood, Westbury-upon-Trym, Hon. Sec.
GLASGOW. March 29th, May 10th, and September 12th and 13th. Mr. F. Gilh. Doughall, 167, Canning Street, Sec.
ROYAL CALEDONIAN HORTICULTURAL SOCIETY. Shows April 5th, July 5th, and September 18th.
WESTMINSTER AQUARIUM. April 12th and 13th, May 10th and 11th, May 30th and 31st, July 5th and 6th.
TIVERTON. May 24th and 25th. Messrs. A. Payne and J. Mills, Hon. Secs.
MANCHESTER (Grand National). June 2nd to 9th. Mr. Bruce Findlay, Royal Botanic Garden, Sec.
SOUTHAMPTON. June 5th, and August the 5th and 7th. Mr. C. S. Fudge, 39, York Street, Sec.
MAIDSTONE (Roses). June 21st. Mr. Hubert Bensted, Rockstow, Maidstone, Sec.
SPALDING. June 21st and 22nd. Mr. G. Kingston, Sec.
BRIGATS (Roses). June 24th. Mr. J. Payne, Treasurer.
LEEDS. June 28th, 29th, and 30th. Mr. James Birkbeck, Delph Lane, Woodhouse, Leeds, Sec.
RICHMOND. June 29th. Mr. A. Chancellor, Hon. Sec.
FROME (Roses). June 29th. Mr. A. R. Bally, Hon. Sec.
SOUTHPORT. July 5th, 6th, 7th, and 8th. Mr. E. Martin, Sec.
HLENNESBURGH (Roses). July 12th and 13th. Mr. J. Mitchell, Sec.
WIMBLEDON. July 12th and 13th. Mr. P. Appleby, 6, Linden Cottages, Hon. Sec.
KILMARNOCK. Roses, July 13th and 19th. General Exhibition, September 14th. Mr. M. Smith, 11, King Street, Sec.

TRADE CATALOGUES RECEIVED.

J. Coombs, The Ferns, Enfield, Middlesex.—*Catalogue of Cuttings of Geraniums, Chrysanthemums, &c.*
 Francis & Arthur Dickson & Sons, 106, Eastgate Street, Chester.—*Catalogue of New and Select Farm Seeds.*

TO CORRESPONDENTS.

* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Books (*Delta*).—London's edition of Repton's "Landscape Gardening" will suit you. We do not know the price.

BACK NUMBERS (*A. R. Middlesex*).—You can have those you mention if you enclose 3d., and the "Year-Book" if you enclose 1s. 3d. They will be sent free by post if you restate what you need, and your full direction.

PRICES OF VOLUMES VII. and VIII. OF THE JOURNAL OF HORTICULTURE (*B. K. L.*).—The price is 5s. each.

SEAWEED ON ASPARAGUS BED (*J. W. L.*).—The seaweed will not injure the plants. Point it in with a fork about the middle of the present month, not so deeply as to injure the crowns.

AZALEAS GROWING BEFORE FLOWERING (*Idem*).—It is not unusual for vigorous plants to start into growth before flowering, and is more prevalent in some kinds than in others. It usually arises from the wood not being well ripened, the buds not well developed from the late vigorous growth of the preceding year. The plants occasionally develop the flower buds along with the new shoots being made, and not unfrequently the flower buds do not expand, but become as you say blind. We cannot account for the ends of the leaves being browned except from syringing, the water hanging from the points when the sun fell powerfully upon them. Keane's

"Indoor Gardening" is a useful book for those who have glass structures, and our "Greenhouse" Manual treats of the culture of Azaleas. Post free for 1s. 7½d. and 10d. respectively.

TUBS FOR ORANGE TREES (*H. S.*).—Charring the inside is to be much preferred to either painting it or pitching it.

BEST BEDDING GERANIUMS (*A. B. C.*).—*Deep lilac pink* are Amaranth and Florence Durand. *Deep rich pink*: Mrs. Holden, Concessa Quarto, and Mrs. Fytche. *Light pink*: Mrs. Lowe. *Rose shade*: Rose Bradwardine.

GLADIATORIA HERBA (*E. T. M. W.*).—No classic author mentions a plant by that name. We think it must be applicable to any plant with sword-shaped leaves, such as the Iris and Gladiolus.

VINE SHOOT (*Z. A. B.*).—The brown is natural. We detect nothing wrong.

GREENHOUSE SHADING (*Oilbo*).—If you only require a temporary shade, the best is a roller shade of No. 3 tiffany or floral shading, and it can be raised or lowered at pleasure. It is only from powerful sun that you will require shade for a majority of flowering plants, but Azaleas, Camellias, &c., require permanent shade in summer, and in that case you may paint the interior surface of the glass with a wash formed of whiting brought to the consistence of thin whitewash with skimmed milk.

PROPAGATING CLEMATIS AND PASSIFLORA (*H. B. B.*).—Take the young shoots of both when they are about 4 inches long with a heel of the old wood, making choice of the stubby side shoots, or better those which come from the root, and insert in sandy soil, placing in a bottom heat of 75°, keeping moist, and shaded from bright sun.

PLANTS FOR CONSERVATORY (*H. C.*).—You could not have anything better for the back wall than Camellias, the border being too narrow for Camellias as bushes or pyramids, and they would spoil the wall for climbers. Clematises are not good permanent climbers, but grown in pots and trained on trellises are very fine for conservatory decoration. *Luculia gratissima* and *Habrothamnus fascicularis* are fine wall plants, but we should cover the wall with Camellias. For the pillars, *Kennedy bimaucata variegata*, *Rhynchospermum jasmynoides*, *Sollya linearis*, and *Jasminum gracile* are suitable.

HELIOTROPE FOR WINTER-FLOWERING (*An Old Subscriber*).—To flower in winter it is necessary that the plants have a genial temperature of 50° to 55°, the plants being grown-on through the summer and kept from flowering during that period. Without a stove or forcing house your supply of flowers in winter, especially of plants for table decoration, must be limited. The mildew is due to too close, cold, and moist an atmosphere. We should have a house for furnishing winter flowers and plants.

SEED-SAVING OF CYCLAMEN PERSIUM (*Stourton*).—Impregnate the flowers with a camel's-hair pencil, and keep the plants in a light airy position, duly supplied with water until the seed is ripe, examining the pods daily when they approach maturity, so as to gather them before the seeds are shed. The plants will do well in a light airy position in a greenhouse, or one moderately shaded.

DESTROYING WOOLLYS (*Idem*).—Place a little hay against the wall, and in and beneath the hay the vermin will hide, upon which in the morning may be poured boiling water. The woolly is but enticed by a boiled potato to places where the pouring of boiling water upon them would not do harm to plants.

SOWING GRASS SEEDS, &c. (*P. M.*).—Pampas Grass, Quaking Grass, Feather Grass, Mink, French Marigold, and dwarf Mimulus require to be sown in a compost of turfy loam and leaf soil, and placed in a gentle hotbed; the seedlings to be pricked off when large enough to handle, and planted out, after being hardened off, where they are to remain. The treatment of no less than six plants are asked for at once, and no particulars of the purpose for which they are required is given. It may be that some of them are required to be grown in pots.

SOIL FOR ARAUCARIA IMBRICATA (*Youthful Amateur*).—It prefers a rather strong deep loam, and to promote free growth a little leaf soil may be added. No stones for drainage are necessary, the ground being free from stagnant water by efficient drains 4 feet deep, having efficient outlets.

CULTURE OF SELAGNELLA MARTENI (*Idem*).—We pot ours in rather fibrous peat, with an admixture of silver sand, affording good drainage, and grow them in a warm greenhouse or cool stove temperature, keeping moist and shading from bright sun. Probably your plants will thrive after the potting is recovered from.

EUPHORIA BUTCHERI (*Idem*).—We do not know any plant by the name; but *E. splendens* is a stove plant, and a very useful one, flowering in the spring and early summer months.

CHRYSAETHYMUMS NOT THRIVING (*J. H.*).—We do not think there is anything amiss, only the plants are late, the tendency being in such a case to throw out lateral growths instead of flowering. The only remedy is to take cuttings in November, or as early as they can be had, and winter in a house free from frost, shifting into larger pots as they fill with roots, giving the shift into the blooming pots early in June, so as to have the plants strong and the bloom well advanced before autumn, removing to a light airy house for flowering. The worms will not occasion the evil complained of.

PLANTS FOR COLD GREENHOUSE (*An Old Subscriber*).—We should devote the house to Tree-roses, covering the ends and the wall with the frost-growing kinds. It would, we think, be the best use to which you could put such a house, especially as you can only attend to it during mornings and evenings.

WINTER CUCUMBERS FAILING (*Inquirer*).—In the absence of data we are unable to account for the failure of the Cucumbers, but we presume you can command a bottom heat of 75° and a top heat of 65° at night, and 70° to 75° by day in any weather, and in such case you will be able to have fruit fit to eat in February by seed sown in early September. The other side of the house may be utilised for the growth of Tomatoes and French Beans.

CAMELLIAS AND AZALEAS FOR EARLY FLOWERING (*A Subscriber*).—Repot them if required after flowering, and place in a house with a night temperature of 55° to 60°, and 65° to 75° by day, with a rise from sun heat to 80° or 85°, and free ventilation, maintaining a moist atmosphere and shading from bright sun, continuing in heat until the buds are well set, when the plants should be removed to a cool and airy house, and if introduced to gentle heat in autumn they will flower at an early period. A Cucumber house will be too hot for the plants to be placed in to make growth.

PLANTING HOLLY HEDGES (*F. Appleby*).—Plant during moist weather in April, moving with balls of earth if possible, and watering if dry weather follow.

PINK APPLES WITH TALL CROWNS (X. X.).—A chief cause is too close and moist an atmosphere with a want of light for the plants, they being at too great a distance from the glass and too crowded in the bed. Give them more room, so as to induce a stiff sturdy growth, admitting air freely. You may require both top and front ventilation, but the latter is not to be used except to keep the temperature from rising too high. Your plants have too much bottom heat by 20°, whilst the top heat is too little, which will enable you to give but little air, and the plants from the close atmosphere will be tall and weak. 85° to 90° is a proper bottom heat.

STARTING AMARYLLISES TO FLOWER IN JUNE (W. W.).—Repot the plants and place them in heat at the close of the present month, affording bottom heat so as to have a good root action by the time the plants start into growth. You will need to use some judgment in having the plants in flower at the proper time, retarding, if likely to be too early, by keeping them in a lower temperature, or forwarding in a higher if not coming on quickly enough; but a rather slow steady growth will give you the finest flowers.

STOPPING ALLAMANDAS (Idem).—Do not stop them, but allow them to grow, unless the plants are badly furnished, when they may be stopped to induce the production of more shoots. If stopped it should be done at once, but we do not advise it unless absolutely necessary. The same remarks apply to these as to the Amaryllises in retarding or forwarding the bloom as may be necessary.

EARLY-FLOWERING RHODODENDRONS (W. G. C.).—*Scarlet*: Grand Arab, Altacarensis, and Igneusens. *White*: Blanc Superb, Empress Eugénie, and Gloire de Gand. *Pink*: Varium, Limbatum, and Sir Walter Scott. Besides these you might take *dauricum*, yielding a succession of its pale purple or mauve-coloured flowers from January to May, with the brighter purple *dauricum strobiliferum* flowering at the same time, *caucasicum* opening its pretty pale pink trusses in April, the rosy crimson *Broughtoni*, and the bright scarlet *Soleil d'Austerlitz*. Most of the varieties of *caucasicum* may also take rank as early kinds. They range through many shades of colour, such as white, lilac, blush, rose, crimson, and purple.

OLD PASTURE FIELD FOR HAY (Ardentist).—There is nothing to prevent your having a good crop of hay from a field that has been several years used as a pasture; but as you say it is rather uneven, it would be better to lower some of the little hillocks as soon as possible, especially if it be intended to use the hay-cutting machine at the proper cutting time. It would also no doubt improve the crop a good deal if the field had a dressing of manure or compost free from stones, as the latter would have to be poked off before the grass started to grow much. The fact of the grass being coarse is more likely to arise from frequent mowing than from being fed off, as the latter, especially if fed off with sheep, tends to improve the character of the herbage. A friend of ours who had a field much over-run with the Ox-eye Daisy—which, although a pretty object in itself, is very offensive amongst hay—after trying various means to extirpate it by digging-up, &c., had the field closely fed off with sheep one year, and all but completely extirpated the pest. We may, however, remark that where sheep are grazed along with cows and other cattle, it is not so well for the latter; the sheep, eating so much closer to the ground than the cattle can do, get all the finest grass. If the land be good and the season a favourable one you may confidently expect a good crop of hay that has been pasture for so many years, provided it has justice done it, and nothing turned out after it the 1st of March.

BARBE DE CAPUCIN (J. E. B.).—It is only the common *Chicory* bleached. The mode of culture is in all gardening dictionaries. The yellow-bellied flower is *Acacia dealbata*.

FLOWER GARDEN (R. Holsham).—No one can direct how to plant a garden which he has not seen. All we undertake is to advise proposed planting.

FLOWER DUNG (J. W. S.).—It, like all other excrementitious manures, may be applied beneficially to any outdoor growing plant. To your Roses you may apply it; but in what quantity must depend upon whether your bushes are weakly or vigorous.

ROSES ON OWN ROOTS.—A correspondent, G. W. Jessop, would be obliged by "E. B. F." naming the Roses that do not succeed on their own roots.

WINTER SPRING (K. V.).—Stir up the soil with a knife on each side of the row, to ascertain if grubs are preying on the roots.

ROSES GRAFTED ON BRIAR ROOTS (E. K. L.).—The Roses grafted on Briar roots in a cold frame six inches apart, we should harden well off by the middle of May, and then lift very carefully, and transfer to pots if you wish them for pot culture, shading for a time until established, or plant out at more than double the distance they are apart in the bed, and four times the distance between the rows. If shaded and duly watered they will soon recover the removal. If left in the cold frame until autumn they will be injured by growing too closely together.

SOWING PEAS FOR SUCCESSION (A. D.).—William I. and Alpha should be sown at once, they will succeed each other; following with Nelson's Vanguard early in April, Champion of England the third week in April, Maudslayi's Best of All the first week in May, Vetch's Perfection the third week in that month, G. F. Wilson the first week in June, and Omega in the third week of that month; you will be likely to have a good succession, but we should add another sowing of No Plus Ultra the first week in July.

LABOUR REQUIRED FOR GARDEN (Wishing Right).—For the two acres of garden, one acre of kitchen garden, an acre of pleasure ground, and a quarter of an acre of bedding-out, with greenhouse and three frames, a gardener, a labourer or assistant gardener, and a boy or woman in summer, would be sufficient to keep it in good order and high cultivation.

DESTROYING ANTS IN HOTHOUSE (M. F. W.).—Place honey in saucers in places which the ants frequent, removing after a few days, and then mix arsenic with honey, again placing it in their haunts, but be careful to keep it from doing injury otherwise than to the ants.

SOIL FOR CAMELLIAS (Idem).—We use a compost of three parts very fibrous light loam, the top inch of a pasture where the soil is a rich sandy loam chopped-up rather finely, with a fourth part of sandy peat. For large plants the peat is omitted, and we top-dress with dried cowdung.

GERANIUM LEAVES INJURED (Edgfaston).—The leaves are injured by some noxious vapour, probably the fumes escaping from the stove or its chimney or smoke-pipe, or the fire may have had its surface overheated.

NEW MODE OF GROWING GRAPES (A. A.).—We regret we have no recollection of your letter, or that which you refer to. When we receive further notes on the mode they will be published.

DESTROYING MOLES (R. H. A.).—Trapping is the best means of riddance. It is said that the Dwarf Elder (*Sambucus ebulus*) leaves placed in their

runs will drive them away, as also the leaves of the common Elder (*S. nigra*), they being used in a fresh state. But these only drive them to make a fresh burrow. A correspondent in the *New York Tribune* states that he has completely banished the moles from his corn fields, &c., his "method being to first soak some corn in water, pour the water off and stir-in some strychnine. Drop in some grains in the runs of the moles, and soon the corn will be missed and the moles too."

NAMES OF FRUITS (Ducker & Son).—Downton Pippin. (*Connaught Subscriber*).—1 and 8, Not known; 2, Brabant Bellefleur. (*J. P. Eldwire*).—Fondante de Charente.

NAMES OF PLANTS (Constant Reader).—1, a *Fouquieria*, apparently; 2, *Salvia coccinea*. (*A Subscriber*).—1, *Asplenium fasciculatum*, Forst.; 2, *Pteris flabellata*, Thunb.; 3, *Nephrodium molle*, Desv.; 4, *Asplenium bulbiferum*, Forst.; 5, *Aspidium falcatum* probably, but cannot say without fruit; 6, *Oncidium japonicum*.

POULTRY, BEE, AND PIGEON CHRONICLE.

DUBBING GAME COOKS.

I do not think "SURREY PARSON" can have kept Game fowls, or he would never call dubbing senseless. It is impossible always to provide a run for each cock, and unless that is done you cannot be sure that the two will never fight. I should have lost valuable birds before now had they not been dubbed. Fortunately, being so, they have only been brought to me in a shocking mess, from which they have recovered in about a week. Like "Fitz," I should dub if I never exhibited. If Mr. Crook is sure that we dub our birds in order to qualify them for the pit he can strike the most effectual blow at the practice by getting up prizes for "stilty" birds. Whenever there has been trouble in my poultry yards I have always found the shorter-legged birds had the best of it.

I very much doubt if the Crystal Palace Show would succeed in abolishing dubbing by following "SURREY PARSON'S" advice; they would be more likely to abolish their Game entries. I have the honour to be acquainted with a considerable number of Game breeders, and I think I may say that there is a growing feeling amongst them that Game fowls, as a rule, do not have enough time given to the judging of these classes. If the Palace, then, was alone in insisting upon undubbed birds they would get few entries. If other shows followed their example I believe it would simply end in Game breeders getting up their own shows.

I fear "WILTSHIRE RECTOR" mistakes a postulate for an axiom when he says, "Let it be clearly understood that apologies for dubbing are in reality apologies for cock-fighting. Stamp out the one you stamp out the other." He begs the whole question. I deny the first sentence, and I daresay experience would prove the fallacy of the second. I have no doubt that my Game cooks, were I to let them try, would bring their quarrels to a conclusion as soon as other breeds, but without their combs and wattles they are much less likely to be disfigured and injured than with them, and I am therefore thankful for a custom which renders their accidental *encontres* much less injurious than they would otherwise be.

As for talking about the cruelty of dubbing, it really is rather "straining at a gnat and swallowing a camel" when we pride ourselves on our hunting, fishing, coursing, and shooting.—F. G. DUTTON.

THE ALMOND TUMBLER.

[We extract the following from the address of O. Merck, Esq., President of the National Peristeric Society.]

I would advise those gentlemen who have had little or no experience in this particular variety not to be over-sanguine of reaching the goal of perfection without great care and patience. Their best judgment is needed in crossing the hard and soft-feathered Almonds, the Splashes, the Whole-Feathered, the Agates, and the Kites, all of these being at times necessary to produce a properly marked bird. Now, let me call the attention of our younger members to this fact, that to breed an Almond Pigeon is one thing, and to breed an Almond Tumbler Pigeon is quite another thing. The plumage constitutes the first, which is pretty well known to most of you. The ground colour of the bird should be of a soft yet bright tint, similar to the almond nut-shell, evenly broken all over with black of the jettest colour; on the head there should be fine stencillings gradually increasing in quantity and size as the hackle is approached, there assuming a rich metallic lustre; on the body they should become larger, and give the feather that spangled appearance which is so characteristic of an Almond. The more positive and marked the spangles are, the handsomer it will prove. The flight and tail feathers should each be marked with three colours—viz., almond, black, and white, these as distinct and varied as possible, by which I mean they should not be cut as it were by a bar uniformly across them. So much for this property of feather, and as the bird unquestionably derives its title from it, I have always considered and still maintain that this is its first and chief property; but whether the bird be then

TAILS.—Cock or Hen.—1, 2, and 3, E. A. Seale, who, A. A. Vander Meerach. ANTWERPS.—Short-faced.—Cock or Hen.—1 and 2, H. Yardley, 3, C. Gamon, who, T. Tweedale. Long-faced.—Cock or Hen.—1, R. Seragg, 2, T. Mason, 3, H. W. Johnson. NUNS.—Cock or Hen.—1, W. Brown, 2, A. A. Vander Meerach, 3, E. A. Seale. MAGPIES.—Cock or Hen.—1, F. P. Bailey, 2, E. A. Seale, 3, H. Jacob. LONGEVITY OF BIRDS.

A VALUED friend, the Rev. Father Noethen, has in his possession a Ring-neck Dove which he has owned for nineteen years, and which up to the time of writing is wonderfully prolific and as sprightly as when young. He also states that he has known one specimen to live to the age of thirty years.

The domestic Goose sometimes attains very great age. Some time ago a statement was made in a paper that Geese frequently live to be very old, and at the same time a record was given of one which had attained the age of 128 years.

Mrs. Colrose now owns a Canary which she has had in her possession thirteen years. It was an old bird when it flew from some cage in the vicinity in her window. She has another which she reared which has passed its twenty-first year, and from appearances may live much longer.—(*American Fanciers' Journal*.)

MR. G. SHRIMPTON.—We hear the painful news that another of our poultry fanciers has passed away.—Mr. George Shrimpton of Leighton Buzzard. He was well known as a true fancier. He made Cochins his speciality, and was a good and careful breeder. All who had business with him found him fair and honourable in his dealings. We can speak with confidence ourselves, for perhaps no other fanciers have had more dealings with him.

REFORMATION IN BEE-KEEPING IN THE NORTH OF SCOTLAND.

"THE bee-keepers of Aberdeenshire and Banffshire are in the van of progress and success," or words to the same effect were made by Mr. Pettigrew in his article "Retrospect," in the *Journal of Horticulture* of October 14th last. I was much struck with the remark, and coming as it did from such a high authority on bees, I have often since thought of giving you my account of how we have arrived at our present position.

The parties named in the "Retrospect" in these counties were George Campbell, Nio Pitalligo; Robert Gordon, Garly; Alexander Cockburn, Cairnie, and myself also, of the latter parish. Mr. Campbell will not be referred to in my remarks. He is a bee-keeper, I understand, of over thirty years standing and of great experience, although owing to his distance from us we had not heard of him until two or three years ago. On the other hand, what standing we have attained has been reached in less than six years. I began bee-keeping in 1870, A. Cockburn a year or so after, and R. Gordon about 1872. We have been earnest enough apiarists since, but before that we knew comparatively little if not absolutely nothing about bees. We and many others around us who have made rapid improvements in bee-farming live in the Huntly or Strathgogie district of the above-named counties, and some miles distant from the Great North of Scotland Railway.

About the month of April, 1870, the *Banffshire Journal* contained a review of Mr. Pettigrew's "Handy-Book of Bees," the first edition of which was just then published. This review was so favourable and represented the book in such approving terms that I resolved to have a copy for myself. On ordering the book from a bookseller in Huntly, who had it not in stock, I was cautioned that often the best of a book was contained in a review, and as it cost then 4s. 6d. I should better consider ere I invested. Well, I had considered and resolved to have it. When I perused it I became immensely captivated with the

writer, his writings, and particularly with bees: he appeared so thoroughly acquainted with the subject, the style was clear and comprehensible, his aim appeared so disinterested—namely, to learn beginners, the most timid or ignorant; then the little trouble or expense that seemed necessary in following out the instructions that pervaded every page of the book. For these reasons I resolved, believing every word, to act up to every injunction, and also to have bees in my possession as soon as possible. I accordingly obtained a swarm in the July following.

About the end of the year 1870 the *Banffshire Journal* contained the annual report of Mr. Pettigrew on "Bee-farming;" at the close of this the editor intimated that he would report any course of management, experiments, or results that might be sent him on bees. Some weeks passed, and as no one wrote I ventured to break the silence about the second week of January, 1871, after having been an apiarian for about six months. In this communication four things were stated that I had accomplished, which were believed to be impracticable by every bee-keeper that I had happened to come in contact with—viz., 1, Had driven out bees from among combs and honey without smoking; 2, had united several of these swarms without their fighting; 3, had fed them so that, though at the end of the honey season, they had nearly filled a skep with combs and honey out of sugar and water; and 4th, the said skep was one 16 inches wide and 12 inches deep, inside measure. No other party gave any account through the *Journal*. In course of time some bee-keepers asked through the same *Journal* how my bees were getting on. I replied, and in numerous articles afterwards through the same channel were the new ideas of drumming, uniting, feeding, and big skeps kept before the public. In these communications I invariably gave out that it was by acting up to Mr. Pettigrew's directions that these revolutions in bee-management were accomplished.

The size of the skeps in general use here at that time would average 12 inches wide and 11 inches deep, some bigger and some less, and being bell-shaped, not flat-crowned, they would be just about half as big as a 16-inch skep now so frequently used hereabouts. When I received my first skep of the latter size, the merchant in Keith who had it made to order said, "Well, you may succeed, I hope you will, but I some doubt you." On my leaving and passing along the street I was met by an auctioneer, one whose calling made him acquainted with most of the things in use in the country around. He accosted me thus, "What in the world are you going to do with such a skep?" Its size, so immensely larger than the common kinds, made every beholder predict that a failure would be the result of my efforts to fill it. But my success, although only a beginner, was so that others began to increase the size, and 18 inches by 12 inches, and 20 inches and even 24 inches wide by 12 inches deep, and these requiring ekes at times, are now in use in innumerable places. It may be said, in these northern counties of course the small hives were also asked when required; but what we say is, that the big skep or hive now in use is a chief or the chief cause of the position we now appear to hold among apiculturists. An author says in effect, "Although not disbelieving about these large hives, suffice it to say I have never seen one." Well, I can assure him such are to be seen. I assisted to weigh one last year over 140 lbs. gross weight, and over three guineas was received from a merchant for its honey and comb. Another party has said, "Such should appear at some of the great honey shows." A reasonable enough expectation, but for those who keep bees for profit such an undertaking would be no light matter to have it conveyed some six hundred miles to London.

I cannot refrain from saying, ere I close, that the very egotistical-like manner in which I have had to write this is against my wish, but I could not otherwise, to the best of my knowledge, avoid it and give at the same time an account in connection with the "Handy-Book of Bees," of the great improvement in bee-keeping in the north of Scotland.—JAMES SHEARER, Cairnie, Aberdeenshire.

THE CAPACITY OF BAR-FRAME HIVES.

A CORRESPONDENT (Mr. Eldridge) puts the following question:—"Will Mr. Pettigrew be good enough to say if a frame hive having a capacity of 8000 cubic inches is, in his opinion, that best adapted for the production of super honey? If not, what are his views of the right capacity when super honey is the object in view, and where run honey only is desired?" This is a very important and comprehensive question, and as it is fairly and intelligently placed before us we think it deserves a special answer.

For the production of super honey in large quantity large hives are necessary, but there is great difficulty in finding the size best adapted for this end. I am of opinion that 3500 cubic inches of space in a hive will be very near the point of excellence. Were I going to keep bar-frame hives I would have them made as near as possible to this size, and in shape considerably longer than broad, but the longer shape would not help the bees to store up super honey. The longer shape would secure a larger

supply of pure virgin honeycomb from the hives themselves, for in hives of fourteen and sixteen bars the outside bars would be often filled with pure honeycomb equal to super honey.

It should be borne in mind that hives of any size are generally in good seasons about one-third or one-fourth filled with honey before the bees enter the supers placed on them. Under the best management the combs of hives cannot be wholly preserved for breeding purposes. The outside combs, and indeed parts of all the combs, become loaded with honey frequently before supers are required. Honey stored in combs of course contracts the breeding spaces in the combs. Sufficient breeding space should be afforded to the bees as well as store room, for if breeding space be not given to the bees they have to destroy many eggs, to their own and master's loss, and it may be they are compelled to entertain the question of swarming. While bees have room for both brood and honey, and are not overcrowded in their hives, the question of swarming is not urgently pressed on their attention, neither are they hindered in their work of multiplying numbers and accumulating stores. In hives of less capacity than 8000 cubic inches bees have not room enough for full action. By using ekes we can enlarge our straw hives one-third when necessary, but with bar-framers enlargements cannot be made, except of course by supering, and this is one of the greatest difficulties in properly and successfully managing bees in bar-framers, but the larger they are the less the difficulty will be felt.

Nutt's collateral hives were a failure in every sense, because they were complicated, or in other words had too many partitions in them. A Nutt hive consisted of a central and two side boxes. The bees in the central boxes often swarmed before an ounce of honey was stored in the side or collateral boxes; but suppose the partitions had been removed, making the three boxes into one, how much more roomy, convenient, and natural it would have been for the bees! How few swarms would have been lost! Nutt's hive is brought into view here with the hope that those who use bar-frame hives for the production of honeycomb will see that pure honeycomb may be more abundantly obtained from elongated hives than from square hives, though shape is of less importance than size.

For the production of both super and run honey I would have frame hives with a capacity of 8500 cubic inches. Every year's experience strengthens my faith in the advantages of large hives, both as swarmers and non-swarmers, both for super and run honey. The sooner bee-farmers begin to pull down their barns and build greater the better, for with large storehouses and plenty of harvesters every farmer will be both gratified and satisfied with the produce of his apiary on the return of every season favourable for honey-gathering.—A. PATTISON.

OUR LETTER BOX.

LICE ON FOWLS (L. R. L. J.).—Parasites in fowls are always the result of low condition, consequent on improper food or management. To keep the number of fowls you do in the space you name would require constant attention if they are to be kept in health. It is impossible to do so on a brick floor, assuming that no other will answer your purpose. We should stipulate that it should be covered with at least 8 inches of dry gravel or road grit. The fowls must also have their dust bath under cover. The addition of sulphur is a good one. You must treat your chickens by putting some ointment on all the bare spots, and rubbing some into the roots of the feathers, or you may use oil in the same manner. Kill-off the birds that are most afflicted. No style of feeding is so bad or so unprofitable as that which consists in giving the same amount of food at all times and under all circumstances. Having fixed on the food that seems best fitted, feed with it at stated times so long as the birds will eat. Leave none by them. We advise ground oats or barley meal slaked with water in the morning; the same in the evening or afternoon; some whole corn or house scraps at midday. They must be daily supplied with some growing grass or cleanings or sweepings of the garden. Some lime, chalk, or bricklayer's rubbish should be mixed with it. Any rubbish containing animal or vegetable life may be thrown in at any time, and as the flooring is brick it can be removed and the place swept clean every day. The history of keeping large numbers in small spaces is by painstaking to supply them artificially with that they would get if at liberty in almost unlimited space.

FOWLS FOR EXHIBITION (Notice).—It seems to us that you are trying to do too much for your space. It is better to keep two breeds well than four badly. To breed prize birds the whole space should be given to one breed. You might keep Cocks and either of the others except Dorkings with hope of success. Let one of the two breeds be out in the morning, the other in the afternoon. You would then have barely room for rearing a few chickens. The case would be altered if the wire fence could be raised at intervals, and the fowls have access to the grass fields. For chickens to do well they should be away from the walks of the adults. When all are in the same place the adults steal all the food, and either half starve the chickens or cause unnecessary expense.

DORKING HENS (Old Subscriber).—There is nothing in your description of your birds that a little patience will not remedy. Curious things often occur to a pullet while laying her first eggs. The small eggs you mention are common. The desire to lay and even the getting into the nest are not unusual. Both are unfailing symptoms of coming eggs. Your feeding is as good as need be. The flagged yard would be bad if there were no other outlet, but as the fowls can choose between that and an acre and a half of grass no alteration is necessary.

FAGONS' EGGS UNPRODUCTIVE (E. B. T.).—We have no doubt your failure may be attributed to a dry heated atmosphere. The same causes produce the same result in all hatching. Eggs want moisture to facilitate the exit of the

bird through their shells. Failing if you might as well expect the bird to force its way through an indian rubber bag as through the inner membrane when hardened by heat and drought.

RABBITS FOR PROFIT (O. E.).—We know no Rabbit that will answer your purpose so well as the Hare Rabbit. It is very hardy, breeds freely, and attains a good size while yet very young. Rabbits have never sold so well as during the last twelve months.

COLLATERAL HIVES (Inquirer).—There are various objections to collateral hives which have prevailed to discard their use almost entirely. We had large experience of them in our days of novitiate as bee-keepers, and although the bees worked in the collateral boxes on Nutt's and White's principle (two or three boxes side by side), we found by experience that there was no single advantage alleged in favour of the collateral box which was not more than matched or compensated for in the use of the storifying principle. A great objection to them is the increased room required on stands or in bee houses.

WAX GUIDES FOR COMBS (F. J.).—As it appears that you have no bars to your hives, it will be sufficient for you to form a single ridge of wax foundation. If, as we take it, your object be to oblige your bees to work in a particular direction, for this purpose one guide comb will be found sufficient. Mr. Cheshire's invention appears to be an excellent one, though we have no experience of it. As Mr. Lee of Bagshot manufactures and sells Mr. Cheshire's hives and other bee apparatus, we advise you to apply to him for the information you require.

REMARKS.

- 1st.—Very rainy all day, except for short intervals; at times the rain was rather heavy.
 - 2nd.—Fine early, but rain before 10 A.M., and fine again before noon; fine in the afternoon, but slight rain in the evening.
 - 3rd.—Damp and dull at 9 A.M.; fine in the middle of the day, showery between 5 and 6 P.M., but very bright evening and night.
 - 4th.—Very fine morning, but rain and hail just after mid-day; fine afternoon (day).
 - 5th.—Rain early; fine from 9 to 11 A.M., though showery all the rest of the day.
 - 6th.—Stormy early; very fine and bright by 9 A.M., though the wind continued, and it was showery all day, but fine though still windy at night. Lunar halo 10.30 P.M.
 - 7th.—Fine (except slight showers) all day; the wind high, and the sun bright. Lunar halo 10 to 11 P.M.
- Temperature very similar to the previous week, vegetation advancing rapidly, strong westerly winds.—G. J. SYMONS.

COVENT GARDEN MARKET.—MARCH 8.

A SUPERABUNDANCE of Broccoli from the west and Channel Islands has caused prices of vegetables to have a downward tendency. Quotations for best sorts of Apples are higher. Cobs are in fair demand. Business quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 50.7°; and its night temperature 33.5°.

SYRINGING VINES—FORCED STRAWBERRIES.

TO an old amateur like myself the differences of opinion about the treatment of Vines by the doctors is very remarkable. On page 178, No. 779, in the article of "Doings of the Last and Work for the Present Week," Mr. Douglas says that to syringe the Vines would sadly mar the appearance of the fruit; while Mr. Pearson, no mean authority, in his "Vine Culture" says, "Except when in flower we use the syringe every afternoon, unless the weather be cold and damp, till the Grapes show colour, and I know 'no other way' in which they can be kept free from red spider." Thus we poor amateurs are in a fix, for if we syringe we spoil the bloom of our Grapes, and if we do not syringe we are eaten up with red spider. When first I grew Grapes I had, or rather my Vines had, red spider; then I, under advice, bought a syringe and spoiled my Grapes, each of which had a ring of white round it. Now I neither have red spider nor white rings.

Noticing that Plums and other fruits do not have their bloom destroyed by the pure rain-drops, I came to the conclusion that it was not the water, but something deposited from it that did the injury, and I bought a charcoal filter; this, as soon as the berries are set, is placed on a shelf with a four-gallon can underneath and the tap left open, and I fill it from time to time as I find it empty, cleaning it well out every week. I obtain daily three or four gallons of water quite pure and of the same temperature as the house, and with this my Vines are syringed once or twice a-day according to the warmth and brightness of the day. Since then I have had no red spider, and I find the bloom on the Grapes uninjured.

What I find most troublesome are the blue-bottle flies, which certainly injure the bloom by flying against the bunches, and eat the Grapes as well. My houses are lofty, with circular roofs (Cranston's), and it is no joke climbing up to tack hexagon netting over the ventilators, besides which the flies come in at the doors, and some are perhaps even bred in the house.

I find some Grapes, such as Trentham Black and Royal Muscadine, are very liable to crack, although under the same treatment; others, as Black Hamburgh and Sweet-water, never crack with me. I am unwilling to discard my Trentham Black, as all my friends and myself think it a much better-flavoured Grape than the Black Hamburgh; it is also earlier, and gives me larger and heavier bunches. I find that cutting the laterals below the bunch halfway through with a very fine saw checks the cracking at once, but I think slightly injures the growth of the Grapes, making the berries somewhat smaller than they might otherwise have been.

Here again the doctors differ. One gardener says the border must have been too dry; another, they must be wet; but I found that one Vine planted in an outside border, which was certainly wet enough last year, did not crack at all like the other planted inside, and I cannot

help thinking that both are right, and that possibly at some time or other the inside border might have been a little too dry for a few days, causing the skin of the Grape to become somewhat inelastic; when the border was watered it could not expand with sufficient readiness to take up all the sap, and so the fruit cracked.

These Vines grew last season with great vigour, and even when the fruit was colouring were making fresh growth, so that almost daily I had to stop some growing points, and they were still covered with those spangles of extravasated sap which are always so satisfactory to the eyes of their cultivator.

Most amateurs who grow Vines grow a few Strawberries in pots. I generally grow two or three hundred pots on shelves level with the ventilators, of which there are three at each side of the houses, the entire length of the range. With Black Prince, the earliest and most prolific of our Strawberries, I always produce a good crop; their only fault is they are small—in these days "there are giants"—and I fail to get more than three or four good fruit on Keens' Seedling or British Queen. I am trying this year four different varieties—President, Dr. Hogg, Vicomtesse Héricart de Thury, and Rivers' Eliza, but I see several of these but not one of the Black Prince are blind, and some of them went off when in their blooming pots out of doors with a disease I have not seen before—the leaves and stems turned black, though the roots seemed sound. Cannot some one raise a Strawberry as early and prolific as Black Prince, but a size larger?

I find by thinning the bloom buds to two or three in a truss that the berries are much improved in size. I have generally four or five trusses of fruit on each plant. I consider that the syringe plays a very important part in keeping down red spider and green fly. I stick to Mr. Rivers' prescription of malt dust and horse droppings, which should be rubbed through a fine sieve and mixed in equal proportions. This is placed on the pots as soon as the Strawberries are swelling their first fruit, and the effect is highly satisfactory.—J. R. B.

A RHODODENDRON NURSERY.

HAVING been growers of Rhododendrons for more than thirty years, a few observations from us may be useful. Our nursery is on the edge of Thorne Moor, a peat bog comprising several thousand acres, situated in a low flat district at one time liable to be overflowed by the rivers Trent, Ouse, and Don. The peat is an accumulation of vegetable matter on a submerged forest, varying in depth from 10 to 20 feet. The surface is flat, and is above the level of the adjoining cultivated land, but being very much composed of sphagnum and other mosses, and the surface covered with Heath (*Erica tetralix* and *E. vulgaris*), the water is retained as by a sponge, and until within a few years it was too soft to bear any kind of cattle upon it.

Our first essay at Rhododendron-growing was by the purchase of a single little plant of *R. ponticum* for 5s., which was planted in a small plot cultivated as a garden

by the edge of the waste. Very soon after it was found to have been wilfully stamped upon by some mischievous trespassers. The split branches were collected and stuck into the perpendicular wall of peat that bounded the garden on the north side. Some of them rooted, and three more plants was the result. As years passed on seedlings were found springing up in great numbers; and on a visit from the late Mr. James Backhouse of York, who was much interested in the district, we offered to give him a lot of seedlings, and in return he sent us half a score new plants with splendid foliage, and which grew vigorously, but never flowered, as every severe winter they were cut down to the ground. However, after having them ten or fifteen years they did produce some imperfect scarlet flowers. In the meantime we had purchased some of the best sorts we could procure, and we have raised thousands from seed. We have a trench cut in the solid peat 40 yards long, with three shelves on each side, and on these shelves the seed was sown, and when the whole was covered by a double herring net supported on spars sufficient protection was afforded to produce plants in any quantity, stout, vigorous, and healthy, with no trouble except the labour of transplanting.

Our nursery being low we suffer at times from frost, especially midsummer frosts, when the young shoots are pushing, and also at times injury is done in the autumn from the wood not being fully ripened, otherwise our plants are splendid, the foliage being unusually bold and vigorous. We find seedlings come in very tardily until they are well rooted, then they grow quite fast enough. About four years ago all our plants were kept on ground from which the peat had been mostly cleared off for fuel, the soil of which in some places is hungry white clay, in other parts sand, but all of a very poor quality, and as we use very little tillage of any kind the plants are not forced. Before we had learned by experience, we bought thousands of small seedlings at a low price; these being plucked-up like Cabbage plants had all the fine fibrous roots torn off, and therefore a large per-centage failed or made very slow progress for some years. We have sold plants with a good ball of root in May which have been replanted and flowered well in June.

As to the soil, where grassy sods and open porous soil, not too dry, can be had without chalk or lime the plants will do very well. We have seen good beds on a high chalk cliff where plenty of peat, leaf mould, and sand has been used, and the plants are very flourishing. In clay, sods, leaf mould, sand, or washed gravel should be used, or the plants will not grow bushy, but lose their leaves and show bare stems.

As to the time of flowering it is rare when we cannot find some in flower, seedlings or others. *R. dauricum* was in flower in January, and some branches sent in a box to Scotland opened-out and looked beautiful there for three weeks. This species is now in full flower and unprotected, February 25th. *R. varium* will flower next month; *R. Cunninghami* and others will follow unless the weather—say with frost and afterwards bright sunshine, which has much more effect than dry cold weather—should spoil them.

As *Rhododendrons* are so hardy, so effective, and cheap, it is surprising that they are not more generally planted, as they will succeed where the common Laurel fails. They are capital for game covers, very few of them being eaten by rabbits, and when in flower they are a great ornament to the woods.—W. & J. C. C.

ROSES FROM CUTTINGS.

MR. CAMM is an enthusiastic Rose-grower and exhibitor; his effusions on the subject are always pleasant and generally practical, and probably many an ardent young amateur learns by heart all he has to say. If it were an unknown man who had penned the lines at page 181 I should not have troubled you with these remarks; but when Mr. Camm says "it takes years to form a good Rose tree from a cutting," and thereby leaves the reader to think that it takes many years, I must beg leave to say that it depends on the way in which the work is accomplished. In your number for April 22nd of last year I described my mode of growing Roses from cuttings, or rather not mine, for the hint, as well as many other valuable hints on which my practice is based, was taken from this Journal some eighteen or twenty years ago.

I cannot pretend to lay claim to such a knowledge of the art of exhibiting as Mr. Camm possesses, and I admire his manly way of teaching all he does know instead of keeping it to himself; but Roses are grown for other purposes besides ex-

hibiting, and for all such other purposes I have no hesitation in saying that where there is a good natural Rose soil—i.e., a clayey loam, such as the hedgerow Briar delights in, that Roses on their own roots are decidedly the best. They do not produce a large flower or two and then bid us goodbye, but go on increasing in size and beauty year after year, and produce blooms by the hundred, filling the air with their fragrance.

Last November I planted 250 plants which had been put in as cuttings exactly two years before. They are planted 8 feet apart every way on a border of very stiff soil, and I expect them to nearly cover the ground this coming summer, and that without any tying or pegging. These were selected from some four hundred or more struck at the same time. I have older plants in great numbers which made growths last summer from 6 to 8 feet in length, and although the season was a cold one the wood is tolerably ripe; and what is a special advantage this year, there are dormant buds to prune to, which on standards are rather too scarce.

My pot Roses for forcing are mostly on their own roots, and those which are not so are decidedly inferior to the others. I cannot have the newer kinds this way, but for my purpose old varieties, if they are good, will do just as well.

During the London season I have to supply abundance of flowers for the dinner-table. A table for twenty or more people twice a-week has to be covered, excepting a few inches at the edge, with flowers of one, or at most of two colours, and Roses, of course, are preferable to anything else. On one occasion last year I sent nine hundred blooms of *Gloire de Dijon*; on another as much *Stephanotis* as would fill two bushel baskets, and sufficient pink Roses to make an outside line; at another time it would be crimson Roses, and so on. I say nothing about the taste of such arrangements, I have simply to obey orders.

Now it is plain that such a demand could not be met with a few hundred standards. No; the point to aim at is to have Rose bushes as big as our *Rhododendrons*, which, I am happy to say, I am in a fair way of doing. The flowers may not be up to Mr. Camm's idea of exhibition Roses—we have no time to attend to them sufficiently for that—but still they are very beautiful, and you can cut and come again.

Why not use more Roses in shrubberies and by woodland walks? Have them on their own roots, and do not prune too much. Nearly all the Perpetuals are as hardy as the common Briar if they are not coddled-up. They would not, perhaps, be prettier than the single Briar in like positions, but their flowering season is longer, and they are mostly sweeter.

Rose cuttings of the Perpetual class should not be put in under glass, but more in the way of Gooseberry and Currant cuttings in November, and the wood must be ripe. Teas strike best from half-ripe wood in July and August under hand-lights against a north wall.—WM. TAYLOR.

CULTURE OF HIPPEASTRUM PARDINUM.

THIS fine Amaryllid is now (middle of February) in our stove very beautiful. It is one of the finest introductions made by the Messrs. Veitch from foreign countries, this one being from Peru. The flowers are very large, opening out flat without any, or scarcely any, tube, the whole of the interior being exposed to view, displaying a creamy ground dotted or spotted as finely as the best herbaceous *Calceolaria*. Too much cannot be said in praise of this *Hippeastrum*, and no stove should be without it.

Its easy culture also is a great recommendation, and still further commendatory is its ready propagation by offsets which rise freely from the base of the bulbs; plants in 5-inch pots having four offsets now of a size large enough for potting, which in two years will make flowering bulbs. The plant is strictly evergreen, retaining the old leaves and putting forth new with the rising of the scape, in pleasing contrast to some other *Hippeastrums* which flower on the top of a footstalk with a few leaves rising from the centre, and destitute of that full garniture of foliage which contributes so much to the beauty of the flowers. Small bulbs of 2 inches in diameter flower freely.

I grow the plants in a stove and keep them always moist at the roots, and pot when the maximum of young growth is attained, using a compost of turfy loam with a fourth of old cow dung, and drain efficiently. During growth the watering is of course much more free than when the plants are at rest, but they are never kept dry. A light position is afforded them, and as to air it is regulated by the other occupants of the stove. The flowers are produced in pairs on a rather tall

scape, and are disposed back to back, so that the internal surface of one flower hides as it were the back of the other, presenting so much beauty as to be admirably suited for a small vase in a boudoir and for many other decorative purposes.

I have been keeping *Amarylises* moist at the roots during the resting season, and now they are starting strongly, having foliage several inches high, which will arch freely by the time the flowers are expanded, two scapes just showing from the neck of each bulb; and on turning them out of the pots the ball is a mass of white healthy roots, and altogether superior to the state of plants dried into brownness or almost out of existence, and which have to be restored by bottom heat to enable the scapes to develope with only a modicum of foliage. In their native habitat the plants are evergreen, which can only be a result of the bulbs being in soil with sufficient moisture to maintain the foliage and roots in a fresh state, and prepared, upon the return of moisture to the atmosphere and soil, for a vigorous growth of bloom and foliage.—G. A.

MUSHROOMS.

HACKNEYED, worn-out is writing on the subject of these desirable edibles. Nevertheless, I should like to note a few things respecting them, which may be useful. To be understood I think I ought to submit a section and ground plan. It may be useful to those having a shed and desirous of growing Mushrooms, and enable our *Agaric* savants to follow the Mushroom mycelium so as to account for its vagaries.

Fig. 64.—Section of Mushroom House.

Fig. 64 is a section. *a* is a side bed, the uppermost; *b*, lower bed; *c*, corner bed on the floor; and *d*, corner bed on a level with *b*. The corner beds are shown on the ground plan, fig. 65, at *c* and *d*. The floor bed *e* is used for forcing *Seakale*, *Rhubarb*, *Chicory*, and, if need be, growing Mushrooms, but so as to be in before (and off) the beds *f* in the ground plan are required for the purposes named; and after they are not needed for *Seakale*, &c., forcing, are again available for Mushrooms. We usually fill one of these beds with *Seakale* every fortnight from early November up to the middle of March, so as to meet that coming-in in the open ground; and *Rhubarb* every three weeks from November up to the beginning of March.

The shelves for the Mushroom beds are of flags about 4 inches thick, and supported by 9-inch brick walls, *g*; and the sides, *h*, of 1½-inch deal, and maintained in position by 2-inch uprights, and 6-inch broad, *i*. Light and ventilation is admitted by the skylight *j*; and a wooden shutter is provided to exclude light at *k*. Heat is afforded by 4-inch hot-water pipes. Seale, ½ inch to 1 foot.

Now, the upper bed *a* is usually made up during the early part of September, and is spawned about the middle of the month. It is earthed a week after spawning, and commences

bearing usually in six weeks after earthing; but occasionally it is not in bearing until early December.

The bed *b* is made up in October or early in November, so as to be spawned by the middle of the latter month. The beds *c* and *d* are made up at the same time as *b*, and they come into bearing by the middle of January, *b* being in fully a fortnight before *c* and *d*. These, with *a*, give Mushrooms in six months of the year without renewal, the first dish being had on November 14th, 1874, and last May 26th, 1875; the first dish gathered in 1873, November 1st, and last April 21st, 1874, which is the only time the bearing was not continued into May. In 1873 the bearing was continued to June 12th, the longest time, the bed *a* having commenced bearing in the October preceding.

Fig. 65.—Ground Plan of Mushroom House.

All the beds were made in the same way with a similarity of materials, and the result has been the same in all instances, repeating themselves year after year; but though all the beds are made alike, similar materials employed, and spawn had from one place and used for all the beds alike, there is a vast difference in the produce of the beds, and in the mode of production as well as quality of the Mushrooms. This difference is what I wish to note.

The Mushrooms produced by the bed *a* come up very evenly over the surface, are not disposed in clusters, or rarely, and always so as to admit of their full development without pushing up or aside others to the former's benefit and latter's disaster. They, as a rule, are about half as thick in flesh and half the size of those borne by the other beds, and have rather thin long shanks, the head of the Mushroom inclining to the back wall or southwards, the gills seeking to be exposed to the light, hence the table inclines away from it.

Those produced by *b* rise in a measure in clusters, by which many in the button state are upheaved—lifted, as it were, on the heads or backs of the powerful risers. A majority, however, rise singly, or with room for development. The Mushrooms are double in thickness, and of course weight, size for size, of those produced by the bed *a*.

On both the corner beds, *c* and *d*, the Mushrooms appear and grow in clusters—lumps of buttons—developing in tier-like form one upon another, the upper ones retaining their hold of the soil by the mycelial filaments, and deriving such support as to preserve them, though small, in perceptible growth. The whole have a powerful hold of the soil, requiring considerable force to remove the "heaps." Some of the Mushrooms obtain full development, but many are buttons. One of these "heaps" drew the weigh-beam in their favour at 2½ lbs.

What I wish to have explained is, Why the Mushrooms rise singly are thin and small, though of excellent quality on the upper bed *a*; very thick, fleshy, and twice the size on the bed *b*, with a tendency to cluster; and why they should invariably come in clusters on *c* and *d*, they attaining a full degree of perfection in the cluster state not exhibited by the other beds when clusters appear. I should also like to know

what objection is to be taken to cluster Mushrooms, when "buttons" are held in even higher estimation than the full-developed edible.—G. ASHBY.

ROYAL HORTICULTURAL SOCIETY.

MARCH 15TH.

For several days previous to this, the first Exhibition of the season, the weather had been of the most inclement character—cold winds, rain, hail, and snow alternating, or not uncommonly uniting, creating discomfort and marring enjoyment. Such was the case yesterday morning, and the exhibitors who faced the storm deserved their honours. As the day advanced the clouds dispersed, affording visitors an opportunity of enjoying the Exhibition. The Show was an excellent one, occupying the entire length of the western corridor, and the quality of the plants was generally of a high order. About five hundred Hyacinths were staged of full average merit, imposing by their stateliness and bright and varied colours.

In Class 1, for fifty Hyacinths, single spikes (open), there were only two exhibitors, Messrs. Veitch not competing this year. First honours were won by Messrs. Outbush & Son with dwarf vigorous plants and fine spikes; Messrs. Barr & Sugden, 12, King St., Covent Garden, having the second place. The most noteworthy varieties in these collections were: Whites—La Grandesse, L'Innocence, Alba Maxima, and Pair de l'Europe; Blues—King of the Blues, Baron Von Tuyl, Mimosa, General Havelock, Osar Peter, Lord Palmerston, and Marie; Reds—Prince Albert Victor, Vurbaak, Von Schiller, Lina, Lord Macaulay, and General Pellissier.

In Class 2 for eighteen Hyacinths, single spikes (nurserymen), there were four competitors, first honours again going to Messrs. Outbush & Sons, who staged a very superior collection; Messrs. Osborn & Sons, Fulham, having the second place with excellent examples—Lothair, Leviathan, Osar Peter, Ida, General Havelock, and Von Schiller being remarkably fine. Messrs. James Carter & Co., Crystal Palace Nursery, Perry Hill, being third with dwarf well-grown specimens, Starlight and King of the Blues being exceedingly effective.

In class 3, for twelve Hyacinths (amateurs), there were five competitors, Mr. Douglas worthily occupying his old premier position with plants not more remarkable for their fine spikes than for their bold green foliage. King of the Blues, Von Schiller, Blondin, Fabiola, Mont Blanc, Macaulay, and La Grandesse were the best in this collection, not omitting an unusually fine spike with immense balls of the double blue variety Van Speyk. Mr. Weir, gardener to Mrs. Hodgson, The Elms, Hampstead, was placed second; and Mr. Meerman, gardener to the Misses Christy, Ocombe Wood, Kingston-on-Thames, third with highly creditable collections.

In class 4, for six Hyacinths, new sorts never before exhibited, Messrs. Barr & Sugden were the only exhibitors; but with the exception of a semi-double white variety, Florence Nightingale, they were not superior, or equal, to older varieties. A second prize was awarded the collection.

In the nurserymen's class for twelve pots of Tulips in not less than six kinds, Messrs. Outbush & Sons and Barr & Sugden were the only exhibitors, and were placed in the order named. Both the collections were good, but the Highgate plants were the dwarfest and brightest. The sorts were Vermillion Brilliant, Yellow Pottelbakker, Canary Bird, Joost van Vondel, Proserpine and Keyser's Kroon. Messrs. Barr & Sugden also exhibited a good miscellaneous collection. In the corresponding class for amateurs Mr. Douglas was again in the first place with the best cultivated pots in the Exhibition, Mr. Weir having second honours with pots of great merit. Besides the sorts named in the previous class we note as superior Chrysolora, White Pottelbakker, Roi Pepin, and Queen of Violets.

The Cyclamen classes were very effective. In the class for thirty plants (open) the champion, Mr. Goddard, gardener to H. Little, Esq., Cambridge Villa, Twickenham, sustained his position with massive plants in 6-inch pots, in good condition and variety; Mr. Smith, Baling Dean Nursery, being placed second with smaller but very healthy plants and fine blooms. In the amateurs' class for twelve Cyclamens there were two competitors, each staging splendid plants, Mr. Goddard's being much the largest, and he was awarded the first place; second honours going to Mr. James, gardener to W. F. Watson, Esq., Isleworth, for healthy plants with fine flowers, but the plants were somewhat loose. In the corresponding class for nurserymen Mr. Smith was the only exhibitor, staging plants of remarkable compactness and profusion of bloom. They were worthily awarded the first prize.

For twelve Chinese Primulas, not less than four kinds (amateurs), Mr. James was the only exhibitor. His plants were remarkably vigorous and fine, especially Marquis of Lorne, red; and Princess Louise, white. The first prize was awarded. In the corresponding class for nurserymen, Mr. Dean, Baling, occupied the first place. Some of his varieties had a considerable amount

of scarlet in the flowers, and the blooms were fine and plants good. Messrs. Dobson & Sons, Isleworth, had the second place with good plants. They also exhibited a collection of small plants with unusually large trusses and good flowers. For six hardy Primroses (Acaulis type), single (open), Mr. Dean had the stage to himself. Crimson Banner, Queen of Violets, Fairy Queen, and Charming are the most distinct and best of the varieties. Mr. Dean also occupied the same position in the next class for six hardy Primroses (Polyanthus type, open), and also in the class for six double varieties of the Acaulis type, Double Rose, Double Blush, Double Purple, and Double Primrose are effective. In the Polyanthus type The Bride is the most distinct and useful variety, some of the others not being worthy of their names.

In the class for nine Cinerarias (nurserymen) there was no exhibitor, and in the next class for amateurs the only exhibitor of six plants was Mr. James. These were very dwarf and 18 inches in diameter, but not quite up to the veteran's best style. The varieties were Beauty of Ascot, Pandora, White Queen, Charles Bending, Agrippa, and William Reeves.

Some valuable miscellaneous groups of plants were staged, Messrs. Veitch as usual sustaining their position as growers and exhibitors. The collection of this firm alone made a charming display. It comprised upwards of seventy Roses in 7 and 8-inch pots, consisting of all the best varieties, the plants being singularly fresh and bright considering the earliness of the season and the late dull weather. Near them was a small group of Orchids, consisting of Dendrobies, Odontoglossa, Vandas, a fine plant of Dendrobium glumaceum, Trichopilia suavis in splendid form, Phalaenopsis, Masdevallias, and Cattleyas. Next in the group was a brilliant collection of Amaryllids, at the front of which were pots of Crocuses. They also staged a group of 120 Hyacinths, all in first-class exhibition form. Noticeable amongst them were Argus, blue, white eye, splendid, a great improvement on Lord Melville; Princess Mary of Cambridge, a splendid spike of silvery blue; Garibaldi, fine glowing red; Haydn, mauve; La Grandesse, magnificent white; Bird of Paradise, buff; Disraeli, light blue; Obelisque, yellow; Vurbaak, scarlet; Etna, salmon pink, most beautiful, charming in colour, fine in bells, and sweet; Madame Vander Hoop, massive bells; King of the Blues, rich and fine; General Havelock, fine, black-purple; Princess Beatrice, pale blue and white; Osar Peter, silvery blue; Fabiola, pink; Prince of Wales, pink; Duc de Malakoff, salmon pink, and Mont Blanc; also a hundred pots of Tulips healthy and bright, and good pots of Crocuses.

Mr. B. S. Williams staged a collection of considerable merit. The background was formed of Palms, which were brightened by good plants of Imantophyllum miniatum and Phaius grandiflorus, the margin consisting of Orchids, Ferns, Amaryllides, Cyclamens, and Primulas, the last-named plants being exceeding fine and all in the first condition, worthy of the Exhibition and of Holloway.

A very fresh, clean, and ornamental group of plants was staged by Messrs. Osborn & Son, Fulham. These consisted principally of Palms, Cycads, green Dracenas, having as a front margin fine-foliaged and table plants. Messrs. Osborn also had a collection of fifty Hyacinths, some of the spikes being very fine and all of good average excellence. Messrs. James Carter also staged fifty Hyacinths of superior quality.

Messrs. Rolleston & Sons, Tooting, staged a thoroughly distinct and striking collection consisting of eighteen plants of the floriferous Azalea mollis, about three dozen plants of Boronia megastigma spangled with a profusion of brown bells, and the singular and elegant Grevillea Priessii which was recently awarded a first-class certificate.

Mr. William Paul, Waltham Cross, staged seven boxes containing 180 blooms of Camellias. These flowers, nestling in moss and surrounded with glossy foliage, produced a charming effect. They consisted of the best varieties in cultivation, from the purest white to the richest scarlet, and many pink and white-striped flowers of great merit. We never saw boxes of Roses more attractive than this choice collection of Camellia blooms in upwards of fifty varieties.

Mr. R. Parker, Tooting, exhibited a group of hardy plants, which always attract attention by their distinct forms and charming colours. Iris reticulata was very fine, Helleborus colchicus and H. guttatus, Scilla bifolia rubra very charming, Apocynon distachyon, Hepaticas of sorts, and Primula acauliserulea, a delicate lavender-coloured variety, were the most noteworthy in this collection. Mr. Aldous, florist, Gloucester Road, staged a very gay collection; the Cyclamens, Lilies, Dendrobies, Palms, and other fine-foliaged plants being effective.

A very fine collection of well-kept Apples and Pears comprising about one hundred dishes, also a fruit of the variegated Pine Apple, was exhibited by Mr. Ford, gardener to W. H. Hubbard, Esq., Leonardale, Horsham, and a silver medal was awarded. A similar award was also made to Mr. Wm. Paul for a meritorious collection of fruit.

A gold medal was awarded to Messrs. Veitch & Sons for Hyacinths, Orchids, and Roses; and silver medals were awarded to

Mr. B. S. Williams, Messrs. Rollisson & Sons, Messrs. Osborn and Sons, and Mr. Aldous for collections of plants; and to Mr. W. Paul for boxes of Camellias.

FRUIT COMMITTEE.—Henry Webb, Esq., in the chair. Mr. William Horley, Toddington, Beds, sent a seedling Apple, which was so much past its best that no opinion could be formed of its merits. Mr. W. C. Pearce, Wicken Villa, Stoney Stratford, sent a seedling Apple which was also past its best. Mr. William Paul exhibited a seedling Apple which appeared to possess some merit, but it was past its best, and which it would be desirable to see again. Mr. Miles of Wycombe Abbey exhibited a very fine dish of Cockle's Pippin. Messrs. Hooper & Co. of Covent Garden sent a dish of Alpha Potatoes, which were produced by forcing in the space of two months. The tubers were planted on the 18th January last, and the crop lifted on the 7th March; they were grown in pots in a cool house. Mr. Douglas, Loxford Hall, Essex, sent fruit of St. Michael's Orange grown in a cucumber house at 70° temperature, and they were pronounced to be of the finest flavour. A cultural commendation was awarded. Mr. Douglas also exhibited an Orange tree in a pot, very healthy and bearing thirty ripe fruits.

Dr. Hogg expounded his new classification of Apples, which met with the approval of the Committee, and a recommendation was made to the Council to award a medal to Dr. Hogg for his discovery.

FLORAL COMMITTEE.—R. B. Postans, Esq., in the chair. Messrs. J. Veitch & Sons exhibited seven new hybrid Amaryllises. The best of the batch was Thalia, a magnificent flower of immense proportions and extraordinary breadth of petals. The flowers are 8 inches across, and the petals 2½ inches wide; the colour is crimson, with a purple shade in the centre of the petals; the base of the cup is greenish white. Fine as are the other flowers raised by the Messrs. Veitch, this variety far surpasses them all. Ohio is also a very fine flower, more approaching the "florist" type than any of the others. It is of large size, with the scarlet shade predominating. The above two varieties had first-class certificates awarded to them. The same firm had first-class certificates for Abutilon Darwinii tessellata, a very ornamental variety, having foliage with the markings of A. marmorata and flowering freely in a dwarf state, and Phalaenopsis Veitchii, an undoubted natural hybrid between P. Schilleriana and P. rosea. The leaves have the markings of P. Schilleriana, and the flowers have the characteristics of that species in the markings of the labellum and formation of the lip. Odonoglossum Chestertonii is evidently a natural hybrid from New Grenada and allied to O. Andersonianum; the flowers are well shaped, creamy white with bold brown blotches. Hyacinth Sultan is the best of the dark purple flowers; it has fine-shaped bells and an immense spike. The Shah, light purple, fine bells, close spike. Golden Lion is decidedly the best single yellow; it has fine bells and a close compact spike. All the above received first-class certificates. Messrs. Veitch also exhibited Princess Beatrice, single pale blue, a very fine Hyacinth in the way of Grand Lilas, and Venus de Medici, which is one of the best double Hyacinths. The flowers are rose changing to salmon as they become older.

Dendrobium Heyneanum, and a species of Spathoglottis with drooping primrose flowers were sent by Sir Trevor Lawrence, Bart., Burford Lodge, Dorking. The former had dense clusters of white flowers and would be useful for cutting; a vote of thanks was awarded. Rhododendron Fisher Holmes was sent by Messrs. Fisher Holmes & Co., Sheffield; it is allied to R. Edgworthii, but has smaller leaves. New Hyacinths were sent by Messrs. Outbush of Highgate, but the trusses were too small to judge of their character. Messrs. Carter of High Holborn sent a basket of Primrose Lady A. T aylour; it is the same plant that has usually been grown as P. altaica.

Ornithidium coccineum, an Orchidaceous plant with small scarlet flowers, was sent by Mr. Denning, gardener to Lord Londesborough.

Messrs. Thibaut & Keteleer, nurserymen, Soaux, France, sent a deciduous flowering shrub of striking beauty named Xanthoerans sorbifolia. The young green foliage, like a miniature form of the Mountain Ash, partly encircles dense spikes 5 inches long of bluish white flowers. As a forcing shrub it has claims of undoubted value, and cannot fail to rise rapidly into public favour. A first-class certificate was deservedly awarded. Mr. W. Paul, Waltham Cross, sent a box of twenty-four varieties of cut Roses, very charming; and a vote of thanks was awarded. Mr. Goddard was awarded a first-class certificate for Cyclamen persicum Purple Gem, a splendid variety of singularly rich colour, the flowers also possessing good form. Mr. Edward Bennett, Rabley Nursery, sent Cyclamen Ruby, very large; and striata, a mottled variety. Mr. Dean sent a collection of hardy Primroses, but they were not sufficiently distinct to merit notice; names of Primroses are being somewhat unnecessarily extended.

A botanical certificate was awarded to G. F. Wilson, Esq., F.R.S., Heatherbank, Weybridge, for Claytonia caroliniana, a plant from the Rocky Mountains—a little alpine gem. Mr. Wilson also sent Primula viscosa and Scilla bifolia. Mr. Smith, Edmonton, sent new bedding Geranium Goldfinch.

Mr. Ollerhead, gardener to Sir H. Peck, Bart, Wimbledon House, sent plants which had been recently imported of Dendrobium Wardianum and lituiflorum, each having two fine spikes with splendid flowers; also Phalaenopsis Schilleriana, very fine. A vote of thanks was awarded.

INTRODUCTION OF THE MOSS ROSE.

FOR AN answer to an "INQUIRY" we have referred to many old authorities, and the results of our search are that Parkinson in his "Paradise" published in 1629, Rea in his "Flora" published in 1665, and Bauhin in his "Pinax" published in 1671, enumerate many Roses, but the Moss is not among them. It was introduced or raised in Holland probably at the close of the seventeenth century, for Dr. Martyn in his edition of Miller's "Gardeners' Dictionary" says it is in Furber's catalogue in 1724. We have seen a copy dated 1727; it is entitled "Catalogue of English and Foreign Trees Collected, Increased, and Sold by Robert Furber at his Nursery over-against the Park-Gate at Kensington, near London."

Faulkner in his "History of Fulham" says that Mr. Bench was the first to introduce the Moss Rose into this country, the original plant of which is supposed to have been brought from Holland. Bench lived at South Field Farm near Parson's Green, a farm possessed by his family for two centuries. He was buried in Fulham churchyard, where there is this inscription to his memory on a headstone—"Under this stone are deposited the remains of Nathaniel Bench, late of this parish, gardener, who departed this life Jan. 18th, 1783, aged 101 years." So he may have introduced the Rose before 1724, for in that year he was forty-two years old.

The Moss Rose was first portraited in the "Botanical Magazine," plate 69. It is described as the *Rosa muscosa*, or Moss Rose, and the plate is dated December 1788. Mr. Curtis observes that, though Miller thought it a distinct species, Linnaeus considered it only a variety of *Rosa centifolia*.

RIPENING PEARS.

I SEE by letters in this Journal that my opinion of the Hawthornden Apple tree is corroborated by several correspondents, and I regret that such should be the case, as the Apple is a useful one, especially for cottage gardens.

The discussion of the subject may be of service and produce a remedy. For example, that excellent Pear the Jargonelle is so subject to canker that in some parts of the country it has been abandoned; but a panacea for this evil has been discovered, I believe by Mr. Rivers, to whom we are indebted for many new and good fruits. The Jargonelle, he tells us, by being grafted on the Beurré d'Amanlis will be rendered healthy.

In regard to ripening of Beurré Diel Pear, I have a tree in a sheltered situation on a south wall which has borne large crops every year for seven years past, which have never failed to ripen from October to the end of November. This last season two of the Pears off this tree did not turn yellow till December, and were eaten on New Year's day; they were ripe, but their flavour was not equal to those from the same tree which were ripe in November.

I once saw a recommendation in this Journal from a correspondent (in reply to a complaint about the non-ripening of Knight's Monarch Pear, Brown Beurré ditto) to bury the said Pears in a jar or large flower pot in their own leaves in a cellar for a month or more before bringing them into the dry fruit room. Has this plan been tried? In my early youth I used to treat wild Crab Apples somewhat in that fashion with excellent results—viz., making a hole in a haystack and burying the said Crabs, which when exhumed some two months afterwards had lost their sourness and roughness and become sweet, and not in the least withered or wrinkled. I will not affirm, however, that there was not a taste of hay on them. I ought to mention that my garden lies 450 feet above high-water mark.

Having seen the then new Apple called the Washington highly recommended in several catalogues (Mr. Rivers' among the rest), I wrote to request him to send me one, which he did some two years ago; it bore two or three Apples last season,

and fully maintained its character for flavour, &c. Can you tell me if it has any synonym; or if not, why it should be entirely unnoticed in the new edition of the "Fruit Manual?" Several Apples quite as novel are mentioned in it.—O. E.

NOTES AND GLEANINGS.

In the programme of Exhibitions announced to be held at the Royal Botanic Gardens, Regent's Park, is included an EXHIBITION OF FLOWER BEDS. This is to be held from June 1st to 8th, the prizes being offered by His Serene Highness the Duke of Teck, G.C.B., and the Society. "These designs for geometric and other flower beds and borders are to be laid in actual beds of the natural size on the lawn, and composed of living plants in pots plunged in sand." The new wing of the conservatory is to be opened on the first day of this Exhibition.

— *ABUTILON BOULE DE NEIGE*, which is effective as a sub-tropical decorative plant for the flower garden in summer, is perhaps still more valuable for affording a supply of cut flowers during the winter and early spring months. If the plants are kept growing in a genial temperature they will produce flowers freely at every joint, and these flowers are even more pure in the winter than they are in the summer. They are very valuable for bouquets, vases, &c., and keep fresh for a considerable time in water. White flowers are always in demand, and few plants will produce them more easily and certainly than this chaste white *Abutilon*. Cuttings struck at the present time will make fine plants for flowering in winter.

— *BEGONIA NITIDA* is a valuable old winter and spring-flowering plant, but of a somewhat loose and straggling habit of growth. This characteristic of the plant has been turned to account in an effective manner by Mr. Ollerhead in one of the stoves at Wimbledon House. Plants of this *Begonia* are there grown in large pots, and the shoots are trained to wires on the back wall. This wall is about 9 feet in height, and is completely covered with shining foliage and immense trusses of pinkish white flowers. There are many fine wall and climbing plants in the houses at Wimbledon, but none are nearly so striking at the present time as this *Begonia*. The plants have been flowering all the winter. This beautiful wall of *Begonias* expresses a happy idea well carried out, and is worthy of imitation.

— The gardens at LOXFORD HALL are always both attractive and instructive. In the conservatory the *Camellias* Jubilee, Alba plena, and Fimbriata are in splendid health and bloom, their white flowers being enhanced by the juxtaposition of large plants of *Donkelaarri* and *Chandlerii*. As white *Camellias* the sorts named should be in all collections. The greenhouse is exceedingly gay, the *Hyacinths* and *Tulips* being in "exhibition form;" very beautiful also is *Iris siberica*, while *Primula nivalis* is charming. The vineries also are very promising, the foliage of the Vines being thinly trained, very healthy, and scrupulously clean. The Black Hamburg house, which has produced more "first-prize" fruit than perhaps any house of its size in England, is not this year likely to perfect bunches quite so large as usual; but the adjoining Muscat house is showing a splendid crop. The berries have set as freely as Black Hamburgs, even the Canon Hall Muscat having several full bunches. There is something of interest also for *Auricula* growers. Never were the Loxford plants in better condition. But more noticeable than the established plants are the fine batches of seedlings. Many of these are showing their first trusses, and other seedlings are springing up as "thick as Oress." From the fact that these seedlings are the result of intercrossing the best varieties, and especially varieties that have proved to be the best "breeders," something really new and good may be anticipated. The fruit crops indoors and out are highly promising, and good gardening and neatness everywhere prevail. A stroll through the houses and gardens at Loxford attests that Mr. Douglas practises all that he teaches.

— A VERY good authority, resident in Cornwall and in a district where RABBITS abound, says that they will NOT EAT ANY OF THE LILIES. They occasionally nibble off a leaf, but the flavour is not agreeable to them, and they leave it.

— THE WIMBLEDON GARDENERS' SOCIETY held their third meeting in the Lecture Hall on Wednesday evening, March 8th, Mr. Lyne, gardener to A. Schlusser, Esq., Belvedere, in the chair. Mr. Jordan read a paper on the cultivation of *Eucharis amazonica*; after which Mr. Ollerhead read a short article on the same subject, which led to a very pleasant discussion. Mr.

Ollerhead also read a paper on the cultivation of *Analea indica*, which created a spirited debate. [We shall publish this paper next week.] Votes of thanks to the Chairman, Mr. Jordan, and Mr. Ollerhead, brought a very enjoyable evening to a close. Several new members have joined the Society.

— THE nineteenth annual Exhibition of the CLAY CROSS HORTICULTURAL SOCIETY is announced to be held on August 15th. Prizes of £25, £20, £15, £10, and £5 are offered for twenty plants, the competition being "open to all England." The total amount offered in prizes is £863. Mr. Stollard is the Secretary.

— YORKSHIRE has long been noted for the excellence of its horticultural exhibitions, and many successful gatherings are anticipated during the ensuing season. Tempting schedules are arranged by the LEECHES and YORK SOCIETIES, the Exhibition of the former commencing on June 28th, with prizes amounting to £500; and of the latter the "grand floral fête" commencing on June 16th, when nearly £600 will be offered in prizes.

— In the "Annales de Chimie et de Physique" for January, M. Dumas has a valuable paper entitled "STUDIES ON PHYLLOXERA AND SULPHO-CARBONATES," which may be taken as representing the present state of the Phylloxera question. His conclusions are briefly as follows: With regard to the Phylloxera of the roots—1, Sulpho-carbonate of potassium is a rapid insecticide, the only one which surely destroys the insect at the roots, and also supplies to the Vine a strong reconstituent element. 2, Sulpho-carbonate of sodium offers the same advantages used only as insecticide. 3, Sulpho-carbonate of barium, being anhydrous and little soluble, is recommended for its resistance to the action of oxygen and of carbonic acid, so that it is a poison less prompt but more durable in effect. With regard to the winter eggs—4, The heavy oil of gas tar, and especially the oil called anthracene, seem to be best for washing the stocks and destroying the eggs. 5, The treatment with tar for the stocks and sulpho-carbonates for the roots, should be effected especially in February and March.

— A good authority writes to us, "Do not advise your readers to make the CEMENT in the way described by the 'Engineer' (page 198), for if they follow the instructions therein specified they will soon find to their cost that split sockets are rather expensive to replace, while the annoyance and risk attending leaky joints will cause much anxiety to the proprietor. Better by far advocate the use of indiarubber ring joints, which can be used in any sockets of hot-water pipes, even those immediately next the boiler, and are perfectly water-tight even under severe pressure."

GUINEA FELLOWS OF THE ROYAL HORTICULTURAL SOCIETY.

In the verbatim account of the proceedings of the Royal Horticultural Society's last meeting, furnished by our Journal, there is one remark made by Mr. Wilson (I presume the 'Lily Wilson'), which is of much interest to horticulturists living in the country. He proposes that country Fellows shall be admitted on a payment of one guinea per annum. At present we pay two guineas, and I think that such a sum is out of all proportion to the benefits which we receive from being Fellows. Take my case for instance. I never go near South Kensington except on the day of the Rose Show (and this year there is no proper exhibition of that flower). My pass as an exhibitor admits me, so I really gain no advantage except that I can go and read, and I suppose write, in the reading-room if I know where to find it; but as I never knew there was one until I saw it mentioned in the list of privileges of Fellows I have not, as can be easily imagined, availed myself as yet of that privilege. I cannot send a ticket for the Rose Show to any friend, because the packet of tickets only admits on days when there is nothing to see or hear. These packets, too, are now things of the past.

I rejoice exceedingly that there is a chance now of the Society's tiding over its difficulties, and I cannot but think that a liberal treatment of country Fellows would do more to help the Society than anything else. The principle of making a difference between the subscription of town and country members is already acknowledged by a few of the clubs, and should be ceded by all. There are numbers of men who would pay a guinea who will not pay two guineas. The Royal Agricultural Society, of which I am a Fellow, only

requires a guinea subscription, and for that you have the same privileges as at the Royal Horticultural Society.

I hope, therefore, the Council will adopt Mr. Wilson's suggestion, for I feel confident that if they do the accession of new Fellows will be large.—JOHN B. M. CAMM.

SIMPLICITY OF ARRANGEMENT IN FLOWER BEDS.

A HEXAGON—A BORDER—A SCROLL.

For a copyist of the somewhat complicated designs of the carpet beds in the public gardens of the metropolis to be really successful, it is indispensable that he should possess an abundant stock of plants and sufficient knowledge of geometry to enable him to trace the figures with accuracy. Given these, with a certain amount of manipulative skill and good taste, there is no reason why a private garden may not equal or even excel any of the public gardens, as was so strikingly demonstrated by Mr. Legg at Cleveland House last season. In the majority of small gardens, however, such facilities do not exist; restricted means, such as want of space under glass, and perhaps only a factotum to make the most of that space, quite preclude any such ambitious attempts; the proprietors acting wisely and well to confine their efforts to a few good sorts of plants, not necessarily the newest or most fashionable, blended together in simple designs, easily arranged and kept in order. Under such a guise their gardens are much more beautiful, and—mark the term!—really enjoyable than they could be under a more elaborate but less successful system of decoration.

Fig. 66.

SUMMER.

- | | |
|--------------------------------------|------------------------------|
| 1. <i>Echeveria secunda</i> glauca. | 8. Golden Pyrethrum. |
| 2. <i>Alternanthera versicolor</i> . | 4. <i>Lobelia speciosa</i> . |

WINTER.

1. *Sedum glaucum*, dotted with blue Crocus.
2. *Sempervivum californicum*, with white Crocus.
3. *Ajuga reptans* and yellow Crocus.
4. Golden Pyrethrum and deep purple Crocus.

SPRING.

1. *Saponaria calabrica*, with the entire centre of *Myosotis sylvatica*. The planting of these to immediately follow the flowering of the Crocus.

The class of gardens to which I allude is an extensive one, much more so than those in the hands of skilled practitioners, and I am very much afraid that one's ideas often take so high a flight as to pass quite over the heads of very many whom one would really wish to assist; so I am now going to try and forget Kew, Battersea, and the Crystal Palace, and to offer a few plain hints concerning flower beds simple in design, and containing plants not very new but of easy culture, yet which, taken apart from the merit of novelty, are no unworthy rivals of the latest "sensations," whatever that may be.

"T. O. J." has three beds, a hexagon, a plain scroll, and a parallelogram of 80 feet by 8. We shall, therefore, strive to answer the queries of our correspondent, and also impart information to others, by explaining something of what may be done to embellish each of these beds in spring, summer, and

winter. Figs. 66 and 67 set forth so plainly the planting of a hexagon that no descriptive note is called for.

Although a border of 8 feet is somewhat narrow, it yet affords scope for so many simple designs as to ensure the requisite annual change. Beginning with the straight lines of a formal ribbon pattern, we could manage four distinct bands of blue, grey, crimson, and yellow; or grey, blue, pink and white, ranging through a variety of shades of those colours, taking good care to graduate the plants with reference to their growth from back to front, or from sides to centre. For example, a border along the verge of a shrub belt might have *Mesembryanthemum cordifolium variegatum* with its charming pale yellow variegation for the front line; next might come the deep crimson *Iresine*, then the sprightly grey *Leucophyton Brownii*, or the soft grey *Gnaphalium lanatum*, with the purple-leaved *Chenopodium Atriplicis* or the elegant *Humea elegans* behind. If the border stands out upon turf it might have a margin of *Mesembryanthemum* with an inner line of silvery grey, such as *Cineraria maritima* or *Centaurea rugosina*, with a centre of any favourite kind of scarlet *Lobelia*—always ornamental with crimson stems and foliage of a deeper hue, and imparting much life and brilliancy to a design in autumn, when the flowers of rich liquid scarlet expand abundantly.

Fig. 67.

SUMMER.

1. *Alternanthera amoena*.
2. *Sedum glaucum*, dotted with *Nertera depressa*.
3. *Coleus Verschaffeltii splendens*.
4. Blue *Lobelia*, dotted with *Fuchsia Sunray*.

WINTER.

1. *Sedum glaucum*, with a single specimen of *Saxifraga longifolia* in centre of angles.
 2. *Sempervivum montanum*.
 3. *Sempervivum californicum*.
 4. *Saxifraga nepalensis*.
- This arrangement can of course be dotted with bulbs.

SPRING.

- | | |
|---------------------------------|--------------------------------|
| 1. <i>Nemophila insignis</i> . | 3. <i>Silene pendula</i> alba. |
| 2. <i>Saponaria calabrica</i> . | 4. <i>Myosotis sylvatica</i> . |

As a relief and change from the monotony of straight lines we could form a curved or serpentine band flowing gracefully from end to end of the border along its centre, and yet with its outer curves just touching the sides, which might have an edging of one row of plants of a small glaucous *Echeveria*. The serpentine band would thus form a number of semi-circular spaces, which could be filled with suitable plants. We might have a curved band of *Coleuses* with alternating semicircles of a Golden Tricolor *Geranium* and blue *Lobelia*; or a band of *Polemonium caeruleum variegatum* with pink and blue patches along the sides; or a grey band with any shade of rose, pink, carmine, blue, lilac, or crimson along the sides. A serpentine band of pink *Geranium* Master Christine, with semicircles of the dwarf white variegated *Geranium Little Trot* with its flowers kept picked off would form a charming bed, the combination being more chaste and lovely than almost any other. Such simple yet effective combinations may be wrought out in almost endless variety.

I cannot now afford the time to dwell upon the great beauty

of mixed borders, but I may say to those lacking enough plants for a regular design, Put your plants in irregular order in the bed, intermingling them with clumps of Mignonette, Sweet Peas, Asters, Stocks, and annuals of all kinds, and you will very likely congratulate yourself upon the fine outcome of your necessity, and it is not improbable that you will cling to your mixed border ever afterwards.

A simple scroll bed really calls for very little detail. A margin of *Santolina incana* with a centre of *Alternanthera amœna* would form a lovely carpet. Change it any way you please, having an edging of succulents, with inner rows or bands, only take care to make the central colour predominate. Edgings and bands of succulents are always neat and impart a high finish to a bed.

If you ask what I recommend, I respond, What is your taste? For a rule I can safely venture to tell you not to put a green-leaved succulent plant like *Sempervivum montanum* next to turf, but prefer the dark-tipped *S. californicum* or the pretty yellow and green *Sedum acre elegans*. The pearly *Sedum glaucum* dotted with any of the larger succulent rosette forms is a charming margin, and the blue-leaved *Kleinia repens* is quite one of the best plants as an inner row to it. For winter take the hardy succulents for a carpet, dotting them with bulbs; or you may follow the summer plants with *Silene*, *Myosotis*, *Saponaria*, *Alyssum*, &c.

One word more. If you require an emerald summer carpet take the bright green-leaved *Cerastium arvense*, which was so effective at Battersea last season, and you will attain your object without the incessant care in pinching which is required when *Tagetes* is used.—EDWARD LUCKHURST.

ABOUT POTATOES.

THE idea of March, and not a word of advice given concerning the planting or about Potatoes in the *Journal of Horticulture* this week! "Zounds, my Lords!" At least, that is what Queen Elizabeth is reported to have exclaimed when threatening to revert to her "old Latin" to reinstate a state of things more agreeable to her. I fear, though, for me to revert *apropos* to Potato culture may cause many readers to exclaim, "Oh, ah! old Fenn, you know!" Nevertheless, the apparent nonchalance of the old *Cottage Gardener* in thus excluding a most important matter, at this season especially, makes me arise to supply a blank and to tell how "old Fenn" is just a trifle new. Of course my ground is bastard-trenched, and the manure compost at once worked into the body of the soil as of old, and not allowed to lie on the surface to waste its ammonia in the desert air. No one, young or old (as I find the subject is cropping up again), will persuade me to depart from that practice. I have not had the gaps ground out of my glaive since the battle with Mr. Pearson on the subject, as the blade is become rather worn by being so often resharpened of yore when upholding the ridge-and-trench cultivation of Potatoes. I have no cause to do that now, as the plan has champions galore.

My practice is still to plant upon the surface at 42 inches apart in garden ground, and 8 feet in the field, proceeding to work by merely casting out a couple of inches of soil longitudinally as a shallow drill in which to place the first row of sets, then measure and strain a line, and cast out the soil as before with the spade (or what is better, with a shovel perfectly square at the bottom of its blade) over the sets in the first row, and so on consecutively till the ground is planted. Watch for the first peeping-out of the young shoots, preparatory for which I last year caused some half-worn-out shovels to have their lower corners cut-off at the blacksmith's, and then made red-hot, and to become slightly rounded—formed, in fact, into shovel-scoops.

At the first sign of the leaves breaking into the light of day strain a line from end to end exactly over the row of Potatoes; then, centrally from between the rows, scoop up with the instrument just mentioned, and cover over the line about 2 inches deep with dry friable soil, and so make sure of covering over head and ears, not only those young shoots already apparent, but those others which are not yet visible, but which we may be sure are just about to become so. The line is easily jerked from its bed out of this first slight moulding to become adjusted, and strained over the next row of sets, and so on. A quantity of such work can be done in a day; and what is more, it is certain safety for the young shoots in the event of frosts so likely to happen now, and at the same time it suits the crop so well.

The next operation is to walk backwards and apply a Parke's fork right and left, or up on one side and down the other, of the rows, turning the soil up ridgeways about 9 inches from the sets, so as to leave them growing in a valley, so to speak, 18 inches wide. Their shoots will presently be seen again in line along the centre of these valleys, bursting through their first slight mouldings. And now again no time must be lost, on account of the fear of the frosts, of moulding-up again. It is to be done also with the shovel-scoops, more friable soil being added this time by filling-up the valleys to a level surface, which were formed by the forking; and for their third and final mouldings, when the shoots are again sufficiently grown, the forks may be again applied if the soil is sufficiently holding for them to bite it, or the trenches sufficiently wide to admit them (I use four-tined forks for this final moulding), otherwise, if the soil is too light or crumbling, the shovel-scoops answer admirably. Thus we complete the ridge and form the trench, and so leave the Potatoes to cater for themselves in the future, in the meantime of course eradicating all weeds as they grow; and if the Potatoes are subject to berry I pick off the blossoms. It is very possible, though, for late frosts to threaten us, and when they do the shovel-scoops will prove instant agents to scatter fine soil amongst the foliage from the bottoms of the trenches as a part protective now, as of course moulding overhead from increase of growth is out of the question; still dusty soil scattered over and about the foliage is a protective, and often sufficient to save from slight frosts. The look and feel of the day will generally warn when a frost may be expected at night, and a whole square of Potatoes can have dusty soil slightly scooped from the bottom of the trenches during an afternoon, and in so doing the shovel-scoops will not by reason of their rounded blades endanger the ridges by cutting into their bases. I consider the above culture by giving extra tilth and permeable texture to the soil a great improvement for the ridge-and-trench system.

Again, in lieu of occupying every trench immediately after the above operations (or so soon as the Potatoes are safe from the frosts) with Brussels Sprouts or other of the Brassicas, skip every other trench, for the purpose of walking up and down unobtrusively, for when bent upon examinations of the Potatoes the mind becomes diverted from the plants in the trench and many of them suffer by being trampled upon. This alternate occupation allows also a clear path to work in when forking out the Potatoes from two ridges, or facility when the disease smites the foliage to turn the haulm from two ridges pell-mell into the unoccupied trench. Some advisers seem to fancy this will prevent the disease-spores being washed down to the Potatoes. I forget who it was some years ago that first mooted this recommendation in these pages. I tried it a few times, but to reap no benefit from it. Mr. Fish of Hardwicke recommended a field roller to pass over the tops. I tried a garden roller, but without satisfaction. I think, in short, I have tried almost everything that has been recommended from time to time excepting Mr. Hibberd's "tile." I have not capacity sufficient for that. I trust no more to experimental preventives other than what I have mentioned above; and as soon as the haulm becomes stricken by disease up come my Potatoes. Of this anon, as I fulfil a promise I made to you last June, page 490, when I detailed the behaviour of my crops and said I would write you again when I had experienced the worst that was likely to happen to them.

Three-fourths of my American sorts had then already succumbed to the new phase, and two-thirds of those which were left had a *Peronospora* quietus, thus proving a most unfortunate enterprise for me. None of my English kinds were attacked by the early curl, but I could have pointed out to you whole plots of some English sorts in this neighbourhood with bad symptoms of our old English friend "Bobbins Joans" accruing from seed which I knew had been heated in heaps, badly grown out, then spurted, and afterwards cut into sets, and I know this old plan is not uncommon even now; therefore we must not always jump to a conclusion as most people did concerning the above, and lump the two features together as being derived from the same cause.

Well, I told you in No. 743 how I came to rent some gardens in old Woodstock last spring. Temporarily, too, in regard to having to move my family I took the house attached to the gardens—and it is a house with a history, by consequence of containing the room in which Edward the Black Prince was born; and it may be interesting to you when I say it looks on to the house and garden where once lived Kemster the cobbler, who raised the Blenheim Orange Pippin. I remember

the last days of the tree, but I was not in time to secure a fragment of it as a memento when I learnt it was cut down—the fire had done its work on the rare old trunk. It is rather remarkable that Haigh and Kemster, both cobblers, should have handed down to us one of the best Potatoes and one of the best Apples that we possess. Peace to their manes! But I thought it rather hard when I read "Blenheim Orange," monopolising the name, and poor old Kemster put down in the middle of a lot of aliases in a contemporary a few weeks since. Such is the way of the world. I have been led into a digression, but I made mention of my house more than anything else for analogy of soil with my other holdings; and we may presume the gardens belonging to it have been under some sort of cultivation verging upon six hundred years. I had the ground bastard-trenched and composted well with a collection of dry-earth-closet soil, and just before I planted the Potatoes had it surfaced with lime quick from the kiln at the rate of a hundred bushels per acre. One garden I reserved for the Americans, and in the other I grew my new four-year-old seedlings now under probation, and had both gardens under the ridge-and-trench plan. No Potatoes could have given greater promise than my new seedlings, and if the season had kept on propitiously I should have tried to have bribed you to come and see them; but fully three weeks before they had arrived at their prime the rains descended and the disease smote them in the haulm, which caused me to "pipe all hands" and have the tubers out of the ground, wet or dry as we could, and as quickly as possible, or you may depend upon it I should not now have so fine a sample of seed to look upon as I possess, comprising the one-third out of the American sorts; and I lost about one-sixth of my seedlings from old Woodstock, if loss it can be called, as I boiled down every specked tuber directly after they were taken up, slightly salted them, rammed them into an old water-barrel, and kept a keen eye upon the sound stock as they lay thinly spread-out in a loft. By thus proceeding I did not have two pecks of my English sorts all through the season that were unuseable, and those I burnt in the copper furnace to assist in boiling their less affected prototypes.

After finishing the garden liftings I immediately turned my attention to the fields, as the haulm of my seedlings there was becoming affected. I found the tubers much worse diseased there than they were in my garden grounds. This caused me again "to pipe all hands," and fork all out with the utmost dispatch possible, the ridges and the unoccupied alternate trenches facilitating admirably. On visiting the diggers next day I was most agreeably surprised, for, excepting about a dozen square yards at each of the places I previously probed, the Potatoes were nearly free from the murrain. Upon inquiry I learned that upon those superfines I made probing upon, near to the gate, had been "shot" some loads of crude night soil a year or so previously. Nevertheless, I told the men to keep on taking-up the Potatoes as sprinklings of diseased tubers kept making themselves manifest. I had in result, however, good cause for congratulation. My Onwards seedling turned out the finest crop I ever had of it, and my Bountiful along with it, and also a good many sorts of my newer seedlings were quite free, and a finer lot of Rector of Woodstock could not be—too large in their tubers, in fact, taken as a whole to please me, as I care more for a gentleman's table than I do for a lot of huge samples to astonish the natives upon the exhibition table. Thus ends the history of this field. Stay, no not quite so. My very good neighbour Mr. Godden accommodates me by letting me have about an acre of land near home to prove my seedlings upon. Now he had growing in the same field not 100 yards from my plot a large plot of Rector of Woodstock, planted according to the custom of the neighbourhood. His seed was good, and it had been properly kept in single layers and cared for throughout, but to no purpose; the disease smote the haulm, but the Potatoes being planted on the flat too close together, and withal allowed to remain in the ground till the haulm was withered and gone, I do not think my friend was enabled to secure more than a third of the crop in a sound condition. And this was the same with several other kinds, comprising Breadfruit, Lapstones, Paterson's Victorias, Bessie's Prolific, &c., on the same ground. I mention this circumstance hoping it may meet the eyes of your correspondent the "DUNBAR REGENT," and also in order to re-assure "D., Deal," from whom I ask pardon for addressing as "Mr. Deal" when I met him last autumn at the Alexandra Palace.

Again I had last season another large plot of Potatoes much farther afield on the stonebrash, a poor soil which it

runneth not in memory of ever having Potatoes grown there before. I grew mine there specially for seed, and calculated from the circumstances to secure a healthy crop. Not so, however. They were stricken in their haulm as soon and as badly as any, and the tubers became the worst afflicted by consequence of our not being able to take them up till those nearer home out of richer soil were completed lifting. Now here is a moral. Of late years I find that when Potatoes are left in the ground after they are ripe, if their haulm has been ever so free from disease the tubers will incur disease more or less. They may look all right, and they won't go rotten to signify for eating, still they will have contracted disease—zoospores, resting spores. But under the operations of the knife when in use for culinary purposes, internal mealy black spots can frequently be detected throughout their whole internal tissue, but never in those that are taken up early from the soil and before they become quite ripe; and this at any rate warns us not to choose our seed but from early-lifted tubers. I observed when cutting my American Potatoes into sets (large tubers must be cut for planting) last spring, a great many of them looked very mealy as above. I destroyed those showing thus, for although it was before Mr. Worthington Smith had enlightened us I knew it could not be a healthy sign. Those of them which I did plant were of course affected, though not sufficiently so to be detected by the naked eye. I grew the seed myself excepting one sort, the Thorburn's Paragon; and the year before last I left my Potatoes longer in the ground than usual, on account of this freedom from disease and in anticipation of a party of friends coming on a journey of inspection. This was the cause of my American seed becoming spotted, and these spots I strongly suspect are Mr. Worthington Smith's resting spores, and these resting spores came early to life last spring. If the above surmises of mine are correct, and our scientific guides can soon enlighten us, Potato culture can be made soon to resolve itself into more certainty by using seed not perfectly ripened (or even very unripe indeed, such as I showed at the Royal Horticultural Society's Summer Exhibition at Bury St. Edmunds, and planted and wrote advice about the following season). Secure good tilth; take care of the seed during winter by storing it in singly in layers; use early-ripening sorts as a rule; plant on the ridge-and-trench plan; place on good holding soil, and lift the moment the disease strikes the haulm; and here we are beginning to resolve the cultivation of Potatoes into a nutshell.—ROBERT FENN.

OUR BORDER FLOWERS—CUDWEEDS.

Nor very numerous are the members of this family of plants, but there is much about them that is interesting to the cultivator of border flowers, and both on festive and mournful occasions they assist us in accomplishing our designs, and are attractive and emblematical. Seldom do we meet with these plants receiving careful cultivation, but they are generally left to take their chance in obscure corners. It ought not so to be, for there is merit in some of our old favourites the Everlastings. I have often admired a Clover field studded over with *Gnaphalium germanicum*, with its erect habit and woolly appearance; but more attractive still is *Gnaphalium margaritaceum*. If left to its own way it is of straggling habit, but neatly staked it becomes a fine border plant, and requires room to develop itself. It continues long in bloom, affording a good supply of flowers, which are very useful for bouquets and for drying for winter use. *Gnaphalium rectum*, as it is seen in plantations in limestone districts, is a very interesting plant to the collector. There are others, too, of this family that ought to be more frequently met with, and are deserving of far more notice than they are at present receiving.

Gnaphalium Leontopodium carries off the palm. It is a splendid subject for the rockery, and the wonder to me is that it is so seldom met with in cultivation. Well-drained sandy loam with leaf-mould and limestone grit will afford it an element to develop itself in. It may be increased by division in the autumn, and when well established cannot fail to be admired.—VIRIDIAS.

"THE ROSE GARDEN."

I HAVE just received this work, written by Mr. W. Paul. It should be in the hands of all devoted lovers of the Rose. The portraits are lovely and tempting. I fear, however, few of us could grow the Roses as lovely as they are represented. The

portraits are *Maréchal Niel* (frontispiece), confessedly the finest yellow Rose and the choicest. *Star of Waltham*, the best novelty I have seen for some time. It is globular and of most glowing colour. I have bloomed it. The *Crested Moss*, called also *Cristata*; the *Austrian Briar Rose*; *Firebrand*; *Louis Van Houtte*, a splendid Rose as portraited, and also as grown here last year on Mr. Prince's seedling Briars; *Madame La Baronne de Rothschild*; *Peash Blossom*; *St. George*, beautiful as portraited, and also as grown here last year. I shall be greatly mistaken if *Star of Waltham* and *St. George* do not prove to be great acquisitions and two of the very best of the latest Roses introduced. *Souvenir de la Malmaison*, the most valuable of all the light Roses; *Belle Lyonnaise*, most beautiful; *Catherine Mermet*, very beautiful; *Madame Levet*, choice; *Marie Van Houtte*, most beautiful; *Queen of Waltham*, very beautiful. It is here, but I have not yet bloomed it. Such, then, are the portraits. As regards the subject matter, it is that of a most experienced and first-rate rosarian. It is to be wished that persons seeking to direct the public would read this work and also wait for more matured experience.—W. F. RADCLIFFE, *Okeford Fitzpaine*.

APPLE YORKSHIRE ROBIN.

THE Apple "M. H." mentions on pp. 189 and 190 as *Yorkshire Robin* is very probably the same as is known in this neighbourhood as *Robin Knaggs*. The tree is a free grower and a profuse bearer; the fruit being of medium, or rather above medium, size, and coming into use in January or February. I have some in use now which have every appearance of being fit to keep for a couple of months longer. The flesh is very firm and juicy, with slight acidity and pleasant flavour, and is good either for dessert or cooking purposes. The variety is in my opinion a very valuable one, and well worth general cultivation. It appears to be well suited to strong soils generally.—W. W., *Statton-in-Cleveland*.

I AM glad "M. H." has been more successful with his *Hawthornden Apple* than is unfortunately the case in many localities. Undoubtedly, from the free growth made and the necessity for the application of the knife, his trees are upon *Crab* stocks; for upon the *Douglas* stock, though it grows very freely for a time, soon arriving at a bearing state, it grows very little—next to nothing after a few years, canker ensuing. The trees I have on *Crab* stocks, though much cankered, grow strongly. I shall, from the hint had from "M. H.," prune hard, and have no doubt that with an amplitude of foliage the tendency to canker will be overcome.

"Robin," about which "M. H." inquires, is still a hale fellow, not likely to die out for many generations. Many of our local Apples are fast losing their local names, being absorbed in the proper names found for them by the author of the "Fruit Manual." "M. H." will find "Robin" accurately described at page 168 of the last edition of the "Fruit Manual," under the unpretentious title of "Winter Greening," of which the author remarks—"A culinary Apple of first-rate quality, which comes into use in November, and has been known to last under favourable circumstances for two years. The tree is very hardy, a free and good grower, and an abundant bearer"—what I have found it to be in every orchard in which I have seen it.

Other of our local Apples are fast losing their identity. *Copmanthorpe Crab*, for instance, is absorbed in its proper name of *Dutch Mignonne*; but what could have been the reason of the original name of "Coate's" being changed to its present one, though it has had both for over half a century, is past the comprehension of—YORKSHIRE GREENING.

SEEDLING BRIARS AS ROSE STOCKS.

I REMEMBER when *Souvenir de la Malmaison* began to find its way among admirers of Roses that it was looked upon as a gem of the first water. At a flower show where it was exhibited an acquaintance of mine, after the show, begged the bloom in the stand, and to his surprise he discovered a bud on the stem. A stock being found the bud was carefully inserted, and in due time was found all right; introduced into heat it grew rapidly, and seedling Briars being prepared, when all was in readiness budding and grafting commenced, every eye being made available for both purposes, and he was soon rewarded by a good number of one of the noblest Roses of the day.

I have found by experience that seedling Briars make good

stocks for all purposes, and their roots are of the very best for root-grafting. It is of little consequence what mode of grafting is resorted to for root-grafting, many of the strong-growing Roses will afford us good stocks for this purpose, but we all have our fancies.

I find midwinter is a good time for the operation. One of the points to aim at is perfect union and exclusion of air, a gentle bottom heat with careful attention as to air and water, and then there is every chance of success. By this means a stock of Roses may soon be worked-up. There are no flowers that afford us more pleasure than a choice selection of Roses, and they are to be had the year round.—A LOVER OF ROSES.

CULTURE OF PERPETUAL-FLOWERING CARNATIONS.

HAVING been successful in growing these very useful plants I thought a few notes on their cultivation would be useful to your readers, as it is now a good time to commence with the propagation of the plants. I think the *Perpetual-flowering Carnations* are amongst the most beautiful class of plants we have for the conservatory, blooming as they do from October to May, and being so bright in colour and many of the varieties having such a delicate perfume that they are always admired.

I procure all the cuttings I can in the middle of March (and on to the end of April for succession), placing them round the edge of a 60-size pot in some light soil, covering the surface with silver sand, then place them in bottom heat (a hotbed and frame being the best place), where they will be well rooted in ten days or a fortnight. I then pot them off, five plants in a 5-inch pot, in three parts of sandy loam and one of well-decomposed cow dung. The plants are kept close till rooted, and are then placed in a cold frame. When the roots touch the edge of the pots I give them their final shift into 6 or 7-inch pots, placing some half-inch bones over the drainage with a little soot to keep out the worms, and place the plants in a light airy situation till the end of September, when it will be time to house them. I find green fly very troublesome, but a pinch of Scotch snuff dusted amongst them soon makes them disappear.

The sorts I grow are unnamed, being from seedlings; but I find *Empress of Germany* (white) and *Miss Jolliffe* (pink) very good sorts.—E. WILSON.

RINGWOOD HALL,

THE RESIDENCE OF JOHN JAMES BARROW, ESQ.

THIS beautiful modern mansion is situated on a gentle eminence, and commands many pleasant views of the surrounding country. It was built by the late G. Barrow, Esq., about fifty years ago. The gardens were laid out and the glass houses erected by Richard Barrow, Esq., chiefly under the superintendence of Mr. Peteh. Ringwood is in the parish of Staveley, and is three miles from Chesterfield and ten from Sheffield. The district of Staveley is more celebrated for its coal mines and iron works than horticulture. There are thirteen distinct beds of coal, the lowest being 1125 feet below the surface, with ironstone lying between each bed.

Richard Barrow, Esq., was succeeded by his brother James, who took but little interest in the garden department; but the present owner, J. J. Barrow, Esq., has done much, not only to improve and beautify the estate, but also to maintain the gardens in all their original splendour. The carriage entrance is from the Chesterfield road, between sloping banks of evergreens of diversified outline. The shrubs on these banks are not so luxuriant as could be wished, for the soil in which they are growing is composed in a great measure of the refuse from the pit banks.

The carriage front has a north aspect only three-quarters of a mile from the Staveley Works, but the volumes of flame continually vomited up by the blasting furnaces are judiciously concealed by dense belts of trees. The grounds fall by a gentle slope from the mansion, and are separated from the park by a sunken fence which conceals the point of junction where the pleasure grounds end and the park begins. The grounds in the immediate vicinity of the house are not cut up into flower beds, as is too frequently the case, but here and there are dotted fine specimens of evergreens. From the east side of the Hall we obtain views of the long range of hills reaching from Eekington to Bolsover. The ancient castle at the latter place is seen standing on the brow of a steep and lofty hill,

and is an object of great interest to the inhabitants of the surrounding country.

Adjoining the west side of the mansion is the small conservatory 70 feet long and 14 wide. It was all aglow with winter-flowering Begonias, Azaleas, Deutzias, and a countless host of other plants which usually flower at this period. Turning to the left and following a narrow walk we come to a large circular basin of water with a fountain in the centre. The next object that attracts the admiration of the visitor is the Rose arbour 100 feet long. The framework is made of strong iron and will stand the wear of many generations. In the summer season it must be a spot of unsurpassed beauty, for there are Roses of every shade and hue, and such as will please all lovers of the queen of flowers.

This arbour leads to the large conservatory (fig. 68), which may be considered one of the chief features of Ringwood. It

forms half of an octagon, and is 220 feet long. The centre is also octagonal, surmounted by a dome supported by eight pillars of the same form, and is of great external beauty. It is entered by a door at each end and two others in the centre. Under the dome is a large fountain of elaborate workmanship, and surrounded by foliage and flowering plants a scene is produced of a pleasing character. At each end there is a stage filled with such plants in bloom as *Imantophyllum miniatum*, *Eupatoriums*, *Heaths*, *Prunuses*, *Hyacinths*, and other spring-blooming plants. From the stages to the large fountain is a broad border 6 feet wide planted with *Camellias* and other permanent plants. A path formed of Derbyshire flagstones runs all round the conservatory 3 feet wide, and then a narrow border for climbers, &c. In the centre border I observed some *Camellias* 8 and 10 feet high and as much through. The bright glossy appearance of the foliage bore testimony to their

Fig. 68.—THE CONSERVATORY AT RINGWOOD HALL.

robust health, as also did the magnificent flowers with which the plants were laden.

I inquired of Mr. Prince, the head gardener, the cause of his success with these gigantic *Camellias*, when he informed me that the only stimulant employed was occasional doses of soot water. Before watering the borders they were strewn all over with a good coating of soot, which is washed down to the roots with the water. Among the *Camellias* I noticed *Queen of England*, *Imbricata*, *Chandleri elegans*, *Lady Hume's Blush*, *Princess of Prussia*, *Prince Albert*, and *Alba plena*. In vacant places interspersed with the *Camellias* are placed in pots such plants as *Myrtles*, *Cytisuses*, *Aloes*, *Yuccas*, and *Imantophyllums*.

There are several *Fuchsias* planted in the border the plants towering 10 or 12 feet high, and which considerably relieve the monotony of the *Camellias* during the summer season when the *Fuchsias* are bespangled with their long branches of pendant blooms. The narrow border is planted chiefly with *Lycopodium denticulatum*, which gives freshness and coolness to the long promenade. At intervals of 8 feet climbers are planted in the border, and trained up the trellis, and suspended from the rafters overhead. These comprise *Passifloras*, *Loniceras*, *Clematites*, *Eccallonia macrantha*, *Fuchsias*, *Tacsonias*, and *Marchal Nial Rose*.

The terrace in front of the conservatory is 182 feet in length. Many former flower beds have been turfed down, and only a

few beds for flowers remain. A fine pair of *Golden Yews* at the top of the steps leading to the flower garden arrest the attention of the visitor. Passing down these steps we come to the flower garden proper. I saw it in September before the autumn rains and cold nights had robbed it of its beauty; and the least compliment I can pay to Mr. Prince is, that the effect produced was excellent.

To the left of the flower garden is a small orchard of young *Apple* and *Pear* trees in excellent bearing condition. This is separated from the pleasure grounds by a thick belt of shrubs, which answer the twofold purpose of a dividing screen and affording shelter for the fruit trees from the easterly winds. Below this orchard is a small kitchen garden used expressly for early vegetables and salads. On turning to the right I noticed another belt of shrubs, which forms the boundary on the western side of the flower garden. At the bottom of this shrubbery on an elevated site is a large standard *Pear* tree, *Welbeck Bergamot*, which never fails to bear an immense crop of fruit. I mention this fact to show the importance of planting on ground as high as possible, where shelter is also afforded by other trees from boisterous winds.

Leaving the flower garden we arrive at a range of houses 75 feet long in three compartments. The first is a *Peach* house under the trees planted in the front and trained to a trellis under the glass, the kinds being *Royal George* and *Barrington Peaches*, and *Violette Hâtive Nectarine*. The trees

are in excellent condition, being well furnished with young bearing wood from the top to the bottom. The second house is a late vinery, the Vines consisting of Black Alicante, Lady Downe's, and Gros Guillaume. On the 19th of February, when I was there, the Grapes were as fresh and plump as if it had been the beginning of November. The third house is a late vinery with the fruit all gathered and the Vines pruned. The Vines in this house are principally Black Hamburgs, Muscats, and one of Black Alicante. It was from this last-named Vine that Mr. Meredith obtained eyes in the first instance to stock the vineries at Garston, and subsequently other places throughout the country.

Leaving this range, the next house to be inspected is the exotic fernery. Here there is much to interest, but approaching night permitted only a hasty glance. I noticed fine specimens of *Gymnogrammas*, *Dicksonias*, *Aspleniums*, *Adiantums*, *Blechnums*, *Gleichenias*, and *Lycopodiums* of many sorts. The back wall is covered with *Lycopodium denticulatum* and a few stray *Begonias* of the ornamental-foliage section. A large piece of galvanised wire netting the same size as the wall was fastened about 2 inches from the latter. Then the cavity between the netting and the wall was filled with moss and peat, the moss being kept next the netting to keep the peat in its place. The *Lycopodium* was fresh and green, and the *Begonias* dotted here and there had a beautiful effect.

In the frame ground are several ranges of pits each 60 feet long, used for Pines in the early stages of their growth, Cucumbers, Melons, plants for the conservatory, and thousands of bedding plants. In addition to the above ranges of pits there is a Peach case in three divisions, the first division being devoted to Cherries, the second to Victoria and Elruge Nectarines, and one Walburton Admirable Peach, and the third being occupied with one gigantic Royal George Peach.

In another enclosure near Mr. Prince's house is a block of useful span-roofed houses and pits. The houses are uniform in size, 45 feet long and 16 feet wide. The first is partly filled with ordinary greenhouse plants and a large stock of superior plants for the summer flower garden. The next is a plant stove containing some fine specimen *Orotons*, such as *O. angustifolium*, *O. interruptum*, *O. irregulare*, *O. Weissmanni*, and the old *O. variegatum*; *Aphelandra aurantiaca* Rozeii, *Xylophylla latifolia*, *Stephanotis floribunda*, a fine plant of *Adiantum farleyense*, large *Marantas*, *Bougainvilleas*, winter-blooming *Begonias*, and *Dracenas*. The next house is filled with Pines, some of them just pushing into fruit, and others for succession. The plants are remarkably healthy, and are distinguished for thick, sturdy, compact foliage, many of the leaves not being more than 2 feet long. The general appearance of the plants demonstrate that they have received skilful culture. Several ranges of pits are used for early Potatoes, Asparagus, French Beans, Radishes, and Salads.

We now cross the park to the kitchen-garden department. There is a range of seven houses built on a hillside, the ground falling at the rate of 1 foot in 10. Each house is 33 feet long, 16 feet wide, and 12 feet high. They are half-span-roofed and heated by hot water. Though there is a difference of rather more than 8 feet in the level of each house, the circulation of the water is perfectly satisfactory. The first is a Peach house with the trees planted in front and trained to trellises near the glass. The trees are in robust health, and give promise of an abundant crop of fruit. The second house is a vinery replanted last May with Vines struck from eyes by Mr. Prince in February. They had completely filled the house with wood and foliage before autumn, and are now cut down to within a few inches of the ground. The third house is planted with Muscat Vines, now pruned and ready for starting into fresh growth. The fourth is a Peach house. The fifth is a late vinery. The sixth also a vinery, and the last in the range is an orchard house devoted to Plums, Pears, and Figs. Some of the trees are in pots and others planted out. They had produced heavy crops of fruit, and from the vigorous appearance of the trees and the numerous fruit spurs and buds they gave great promise for the future. In the kitchen garden I observed some fine dwarf Apple and Pear trees, and a few standard Plums. Mr. Prince informed me that he saved his crop of Pears and Apples from being destroyed by the frost by tying bunches of hay among the branches. There are several fine beds of Strawberries, and judging from their luxuriant appearance Mr. Prince evidently understands their cultivation. Among Broccoliis Snow's White Winter was found to be invaluable.

I may add that Mr. Prince, the gardener, is thoroughly

practical and master of his profession. He received his early training at Lord Londesborough's at Grimston Park; he also served at Syon House under Mr. Smith, now of Kew, and at Chatsworth. As a garden, both extensive and complete, Ringwood is especially noteworthy, and in my hurried visit I have reluctantly passed over many features of interest with which the place abounds. Mr. Prince is about to leave Ringwood, but a gardener so competent is not likely to be long disengaged.—R.

CELERY AND ITS CULTURE.

THAT this is a very favourite vegetable and one which absorbs a considerable share of the gardener's attention is evident from the efforts which are made by vendors to "select," "improve," and offer "new" sorts having superior claims to public notice.

Celery is one of the most important of our staple garden crops—a crop for which there is no substitute, and one which must have a high system of culture bestowed on it to bring it to perfection. It matters not how small a garden may be, Celery must be there; while in large gardens it is grown almost by the acre, and in "market fields" many hundreds of acres are devoted to its culture.

Further than merely growing Celery for plain table use a healthy rivalry is manifested in perfecting heads of the most attractive appearance for exhibition purposes, and as feats of skill sustaining the cultural reputation of the grower. In some districts—notably in the vicinity of Sheffield and Manchester—the culture of Celery is almost a speciality, and the cultural ability of many amateur gardeners is measured by the manner in which they exhibit at the "Celery show." These exhibitions which are common in the neighbourhoods of manufacturing towns are remarkable for the gigantic and otherwise well-finished "sticks" which the growers produce. It is not unusual to find heads of Celery exhibited upwards of 4 feet in length and weighing from 10 to 12 lbs.

As an exercise in kitchen gardening and as a healthy mode of recreation of artisans and aspiring gardeners, high-class—that is, gigantic—Celery culture is not only permissible but commendable. It calls into action good and useful qualities which are seldom brought out until a man is "put on his metal." Huge and perfect heads of Celery cannot be produced without a rich and highly prepared soil, assiduous and unremitting attention, and hard work. These are qualities which are indispensable to the success of every gardener; and if by an attempt to grow in a "fancy" manner this or any other vegetable these qualities can become fixed as a part of a man's nature, the lesson will prove simply invaluable in after-life. Celery-growing is first-rate educational work; for if a man can win a copper kettle at a great Celery show he is not likely to fail in the cultivation of other vegetables. The hardest race I ever ran and the toughest prize I ever won was in a Celery race near a large town, when I was "first with White and second with Red." I fought then for my craft and not for the prize as such, for the gardeners of the district, it was confidently predicted, would be "nowhere," while I was resolved if possible that they should be "somewhere." I had not taken lessons from my most worthy teacher without being impressed with a feeling to honour my calling, and so far as it lay in my power to make it respected and not despised. Shall I state how I won that coveted prize?

First as to soil. I knew that it must not only be rich but rich in that element that was necessary to sustain the crop. What that element is and where I was to obtain it was not very clear to me, so I went to work in a very primitive fashion in working out a problem of chemistry. I wished to place in the ground not only food for plants but food for Celery. What that food should consist of I took as guidance the previous year's crop, and resolved that what it had took out of the soil I would endeavour to restore. I simply therefore saved all my Celery trimmings and made them the basis of my rot heap and future store. The trimmings were treasured, and as they decayed they were covered with soil—a layer of trimmings and a layer of soil. The mixture was further saturated with the strong drainings of the dunghill, and so the compost was formed which won the prize. I have never grown such Celery since as by that mixture, and hence my reasons for believing that it was rich in Celery food.

Next as to sorts and preparing the plants. The Red was Manchester Red and the White Goodwin's White. The raising of the plants I knew to be an important matter, and that

the usual mode of sowing the seed thickly in seed pans, like raising so many *Lobelias*, would never do. I therefore made a hotbed of manure and leaves, knocked a frame together of four boards to support the lights, covered the bed with 6 inches of rich light soil, and on this bed I sowed the seeds thinly—that is, that the number of seeds which are usually distributed over the surface of a pan a foot in diameter were scattered over a surface of ten times that area. The seedlings came up an inch or two apart, and with the gentle heat below and the gentler heat above, and with light and air surrounding each plant, they were extraordinarily robust. I knew that when my seed was sown in March that at least one of my competitors had plants in pans ready for pricking out, but I was not disconcerted. I knew his plants must receive checks by being twice transplanted, whereas mine were sufficiently thin to grow unchecked during the time that his were “recovering” from removals.

During the first week in May a portion of the plants were transplanted in a bed of rich soil at the foot of a south wall, and in June they were planted in the trenches. Others were left thinly on the seed bed, and were removed from thence to the trenches without any intermediate transplanting. There was no difference in the size of these plants when they were planted, neither in the size or quality of the Celery when it was ready for use. It was not only superior to my neighbouring competitor who sowed his seed in pans in February and grew on his seedlings like so many tender flowers, but it was superior to my own “early row,” the seed of which I had sown under glass occupying much precious room in growing on my young plants.

There is no better mode of raising Celery plants for any purpose than by sowing the seed very thinly on a gentle hotbed, so thinly that the seedlings should not be closer to each other than 3 inches; then do they come strongly, grow sturdily, and only one check is necessitated by transplanting. The hotbed on which the plants are raised comes in useful for ridge Cucumbers, and if a few seeds of these are sown in the bed as soon as the Celery is removed, Cucumbers or, what are perhaps more useful, Gherkins for pickling, will be freely produced in September. If also a few lumps of Mushroom spawn are sprinkled over the bed before placing on it the soil for raising the Celery, it is more than probable that the crop of Gherkins in September will be followed by a crop of Mushrooms in October and November. Thus what at the first glance may be considered an extravagant provision—a 3-foot-high hotbed of leaves and manure for raising Celery plants—is not extravagant at all, but is really an economical mode of growing three crops, any one of which is worth the trouble involved in preparation.

The trenches in which my prize Celery was grown were 18 inches wide and 2 feet deep, and made rich with the compost above mentioned. The plants were regularly watered, and when established—not before—a slight sprinkling of nitrate of soda was given once a week, and washed into the soil. As the plants attained strength soot and guano water was applied freely; indeed the soil was continually moist, and as the roots protruded through the surface they were covered with manure.

The plants were tied up as they advanced in growth, and each was enveloped with brown paper. Celery collars were not then invented. The paper was applied in several folds, and six weeks before the show the earth was applied. The result was the largest, cleanest, and most solid Celery I ever produced, and the labour was not begrudged when the prize was won.

Yet I must rule that that mode of growing Celery for a gentleman's table is a wasteful mode—a waste of manure, ground, time, and labour. Before “sticks” of that character can be presented in the dining-room four-fifths of them must be trimmed away and be sent to the rubbish-heap. My table Celery is produced at fully twenty-five per cent. less cost, and the quality is unimpeachable. My paper is, however, too lengthy for further details, and I will only say that the kinds I find most satisfactory for everyday use, and not for exhibition, are Turner's Incomparable White and Hood's Dwarf Red. Sorts larger than these, and altogether good, are: Reds, Ivery's Nonsuch and Leicester Reds; Whites, Veitch's Solid White and Dixon's Mammoth. These are suitable for home use and exhibition. When large heads are especially coveted I recommend as Reds Wright's Grove Red and Manchester Red, and as Whites Wright's Grove White and Goodwin's White.

For any purpose I advise that the seed be sown very thinly on a slight hotbed. If this cannot be had then make a seed bed 6 inches deep of thoroughly decayed manure or leaf soil in a very sheltered place, sowing the seed thinly at the present

time, and protect with glass. This is much preferable to sowing thickly in pots and raising quickly in heat, which is productive, unless special care is exercised, of a large percentage of “bolted” plants. I will return to the subject of Celery culture on a future occasion.—B. FISH'S PUPIL.

FRUIT-TREE COPINGS, &c.—No. 8.

I FIND that though copings are a great assistance in early summer to keep insect life in abatement by accelerating the quick growth of young wood, yet after a certain time (according to season) it will at once be made apparent by the condition of the trees that the copings must be considered a great disadvantage if they are fixtures. Perhaps this may not be the case in cold-lying situations; I should not have found it so at Maesgwynne in Carmarthenshire, still in four situations out of six portable copings will be found the best. It is possible—nay, probable, that in one season in a half dozen we may find it of advantage if the coping were to remain on all the year. This brings to my mind that I hope to see the day when we shall have a sliding coping, so that by a mere pull we can have it down or up as required.

But to pass on to the more immediate subject. I find after the foliage has grown to its full size or nearly so, and fruit is “out of danger,” that dry winds and a powerful sun are drawing from the supplying sources of the tree. There is a stream that cannot be well met. Insects are now busy setting to work, and the glass coping that in spring fostered a rapid growth to the deterioration of insects is now doing the reverse. Red spider takes possession of the tree. Those invigorating dews, that passing shower—at once life to the tree and death to the insects—are kept from their life-giving mission—by what? The coping. Can we draw a comparison between glass coping and glass houses? Really there is nothing in common between them. Why? The glass house keeps off dews and showers I admit; but we can moisten the beds, walks, &c., in a house, and the wind has little or no effect in carrying it away. Not so the borders under coping. Moreover in syringing the trees in a house we find the moisture to remain for a considerable time. Not so on the trees under coping. In fact, I cannot see the good of having the coping on all the summer.

My experience last summer somewhat differs from the opinion that glass is a non-conductor. Trees under glass coping here require a far greater supply of water than those without coping; still worse, I found red spider more troublesome than the year before, though one was an extra dry, the other an uncommonly wet year. Judging from this, one is brought to think that glass coping must extract moisture both from the foliage and of course from the soil. If I am right, this again points to portable coping as the proper thing. Have a coping of, say, 2 feet 6 inches wide over trees growing in a dry situation, and it is easy to predict a short life for them if they are not very carefully treated.

There is another most disastrous practice if not avoided which is likely to bring coping into disrepute—namely, by not allowing space for ventilation at the apex. It is astonishing the power of heat that accumulates under a 2-foot-6-inch glass coping under a bright sun, and if it has no escape will do irreparable damage by roasting the foliage and wood and increasing red spider. I find even with an aperture of 1½-inch with a fixed coping that it is difficult to keep down red spider for a foot or so on the top of the trees. I would not have less than 3-inch ventilators from one end to the other. The question will be asked, How are we to keep out the frost and rain if we give this ventilation? I presume that most, if not all, walls have a stone coping of from 3 to 4 inches at least. Under this, then, is the place for the glass to be placed, leaving the space required for ventilation. The dropping of water from off the stone coping must be carried away by its overlapping the glass for an inch or two.

We now want to provide against driving rains, wind, and frost. A perfect glass coping is yet desirable. At times we want all snug and close, at other times a good proportion of air playing on all parts of the tree is indispensable. I find the most economical and effectual way of placing the screen is by having a row of galvanised hooks screwed in the front of the coping at, say, 3 feet apart. I like good tiffany for the screen; it seems to keep out frost well, and is less cumbersome than many articles, and is soon dried after a wet night. I have it made up in long lengths and bound with strong wide tape to which is sewn brass or galvanised rings on one side to correspond with hooks in front of the coping. The other side of

the screen we sew on good strong cords just long enough to tie to a rail placed within an inch or two of the ground. A man can place this screen or remove it in a very short time with a rod similar to those used by a shopman to place his shading over the window. When this screen is once up and tied at the bottom nothing will move it. It is pleasant to walk along inside when very boisterous without, and find how snug all is. You can watch the unfolding of the flowers and swelling of the fruit. One can disbud sooner, and tend to the many other little matters, not leaving out the attention to hardening-off bedding stuff or earthing-up the few early Potatoes growing under the wall, all without exposing oneself to the outside wind, rain, &c. I find a narrow batten of wood a handy means of stopping-up the ventilating openings when required. If just a little tight it can be driven in easily, and removed quickly when not wanted.—JOHN TAYLOR, *Hardwicke Grange*.

KILLING RED SPIDER.

ONE of the best means of eradicating this pest, and one which I have successfully practised for many years, is by creating fumes of sulphur with the aid of heated furnace shovels. If the operation is performed with due care every spider will be killed, and not a leaf of either Vines or Cucumbers will be injured. If, however, the work is loosely or carelessly done injury will inevitably be committed. But of this there is no real danger, for a safety valve is always present, which if regarded will lead to satisfactory results. My mode is as follows:—

On the evening of a still day, and after the house containing the spider has been closed, I secure the aid of two assistants. One heats a shovel at the fire, and runs with it to the door of the vinery. Here is placed a careful man with a pot of sulphur, which he sprinkles very slightly on the shovel, and the sulphur at first burns with a flame. That is the danger signal. In a few moments, however, the shovel cools and the sulphur smoulders, showing no incandescence whatever—that is the safety valve. At that stage he hands it to me inside the house, and I sprinkle it freely, and continue to do so as long as fumes are emitted. In the meantime other shovels are being prepared outside. In a quarter of an hour I have a light blue atmosphere, and as soon as my eyes commence smarting I leave the house.

In the morning I have invariably found every red spider dead, and every leaf alive and uninjured. The slightest incandescence of the sulphur inside the house will cause injury to the foliage, but I have never found the slightest harm result if the precautions named have been duly carried out. It is a matter on which none need err, for it is easy to perceive when the sulphur does not show a flame outside, and as easy to know when one's eyes smart inside the house. I have practised the plan for more than twenty years, and always with the same result of killing the spider and not injuring the foliage of Vines, Cucumbers, or Melons.—G. W. Y.

[We insert this letter, knowing the writer to be an able and experienced gardener; but we think it right to urge that great care is needful in carrying out the plan which he details, and on no account should it be attempted by young and inexperienced men.—EDS.]

NOTES ON VILLA AND SUBURBAN GARDENING.

GREENHOUSE AND FRAMES.—The first-named structure will now be gay with many plants in flower, and as they come in let them have the most airy part of the house, guarding, however, against any sudden change of temperature. What I mean is that after a plant has been forced, even if it is only moderately, the change from heat to a cooler atmosphere will frequently cause the plant to flag, and the result is that many of the undeveloped flowers do not expand at all, so that the fickle weather of March must be watched and air given accordingly.

There is as much or more skill in completing the growth of a plant after it has flowered than there is in bringing it into flower. I allude to such plants as Asaleas, Camellias, Deutzias, Heaths, and such other plants as an amateur grows in a general way. Some, such as the above, make their growth after flowering, and therefore when out of bloom must have a genial atmosphere afforded them to complete that growth so necessary to the next year's flowering; while others which are herbaceous, such as *Dielytras*, *Richardias*, *Solomon's Seal*, and *Lily of the Valley*, and many more plants which make their growth at the time of flowering, must have just as much care taken of them as the first named, and not be thrown aside, as is frequently the case, to take care of themselves. Unless the bulb has proper time

and treatment to grow and mature itself it will not flower successfully next year. So far it has been too cold to do without a little fire heat at night, therefore the sort of plants I mention must be kept at the warmest part of the house and be syringed occasionally; but when fine warm weather sets in the plants may be transferred to the pits or frames, and kept growing by husbanding the sun heat and closing early in the afternoon.

In the matter of bedding plants they may be safely trusted in glass frames now—that is, if they are kept close until better weather sets in. When watering is done let it be in the mornings of fine days if possible, so that the plants may dry themselves before the evening.

Prepare a temporary place for the *Calceolarias* and other similar plants that have been stored in frames; meanwhile, if they are making too much growth, take the tops off, and in a short time they will break again into growth, when they can be planted out in the place above mentioned, and kept protected for a time by day and night, afterwards to be exposed if the weather proves warm and fine.

Propagate at every opportunity all classes of bedding plants, especially those of small or dwarf growth, such as *Alternantheras* and other slow-growing plants. These, after rooting, should be grown in heat; and even the old plants, in order to produce cuttings, may be potted and placed in a *Cucumber frame*; but they ought to grow rapidly and afford a large quantity of cuttings, which will root in a few days.

KITCHEN GARDEN.—Some important crops must be prepared for now. Successive sowings of Peas and Broad Beans must be made as soon as the preceding crops are above ground, and these also must be protected by ridges of earth and a few twigs placed at the windward side of the rows. Peas cannot be had in use too early, and the crop may be accelerated a week by a little assistance in the way of protection in the earliest stages of growth. Spinach may also be sown between the rows of Peas; or, if the ground is scarce, even between the rows of Raspberries. It is a healthy useful vegetable, coming into use quickly after being sown, and should be more frequently seen in amateurs' gardens. A pinch of *Snow's Winter White Broccoli* should be sown at once; it is indispensable in every garden. Brussels Sprouts, Cottagers' Kale, and Savoy are equally serviceable, and seed should be sown without delay. The sowing of later crops of Broccoli may be deferred for a week or two. Sowings should also be made of Cauliflowers, Lettuces, Radishes, not forgetting also a row of Parsley. Potatoes should also be planted except in cold and heavy soils. The sets should be carefully prepared, and be assisted to make a stout sturdy growth before being placed in the ground. In light soils and dry situations plant early and deeply; but in soils of an opposite character it is preferable to prepare the sets and aid them to make a healthy growth above ground, and then plant rather shallow early in April. That applies to clayey ground and cold districts. A little Celery seed should be sown on a gentle hotbed or in pots of light soil. Do not sow any seeds unless the soil is in a free workable state.

FRUIT GARDEN.—The blossom buds are prominent and the weather inclement. Fruit trees on walls must be protected, or there is great danger of the crop of fruit being lost. Sacking, sheeting, netting, straw screens, evergreens, will all be useful aids in producing fruit if applied and also removed at the proper time. The protecting of fruit blossoms is a work of great importance, and the means for fruit-growing are incomplete unless protecting material is provided to shelter the trees against the piercing winds and nipping frosts of spring. Many trees of Apples and Pears produce terminal fruit buds at the extremities of the branches. These must be picked off at once, in order that a wood bud may be induced to break and continue the extension of the tree. Many young trees are greatly injured, if not ruined, by neglect in promptly removing terminal fruit buds.—THOMAS RECORD.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

If the nailing of trees is not finished it ought to be done without delay. The Apricots are in flower on south and east walls, and the protecting material ought to be fixed and ready to place over the trees in an emergency. Anything sufficiently thick in texture will answer the purpose of protection, and it is cheapest in the end to obtain a good article. There is a cheap shading in the market made from jute, or a mixture of jute and flax. We have some shading now which is likely to last made entirely from flax. It costs 6d. a yard, and will be cheaper in the end than the mixture of jute and flax that could be bought 25 per cent. cheaper. There is one thing which should be mentioned, and that is that the best material is made generally but a yard wide, whereas if it could be bought as wide as the wall is high the expense of sewing would be avoided. Whether the wall is covered with protecting material or not, at all events there ought to be a projecting moveable coping which should extend about

a foot out from the wall. It may be of wood, slate, or glass; the former is easiest managed.

Many gardeners are obliged to crop their fruit-tree borders close to the wall. We have seen Cauliflower plants so reared, and various small salads for early use; and spring flowers, especially Violets of sorts, are brought in very early in such a position. It would be much better if the space at least 8 feet from the walls could be free from crops, so that so much of the ground could be covered with decayed manure.

Where the walls are much exposed to gales of wind the placing of evergreen branches amongst the trees as a shelter may be a very doubtful advantage. Some growers, especially the amateur class, are very fond of digging amongst the roots of their trees. If the tree does not bear they say, "Let us dig about it and dung it." Very often it would be better to let the ground alone, and for stone fruits especially. Should the soil be firm the mulching of manure will entice the roots to the surface, and will also prevent the ground from cracking.

The ground is very wet yet, and the Strawberry bed required weeding. A man went over the ground first and picked out all but the very smallest weeds, and on a drying day last week the Dutch hoe was run through between the rows. All ground under fruit trees will be stirred with the Dutch hoe when the ground is dry. Keeping the hoe at work early in the season is very advantageous to all the trees that are not mulched.

ORCHARD HOUSE.

Peach and Nectarine trees are now expanding their blossom buds on the trees in pots. The weather continues cold, but there has been sufficient sunshine to raise the temperature of the house by day, and the high winds are an advantage to the setting of the fruit. When the weather is dull and close it is necessary to gently shake the trees daily to distribute the pollen. The trees require water only about once a week as yet at the roots, and it is well to be careful not to spill any of it about the paths or borders of the house. Pear and Plum trees have been brought in from out of doors. The blossoms of the Pear trees were considerably advanced.

VINERIES.

There is nothing particular to note in this department. In the early houses the flowering period is over, and the fruit seems to have set very well. The Vines had been allowed to grow on unchecked until a few days before the flowering period, when all the laterals were stopped, and until all the bunches had flowered there was no more stopping or tying; either to bend down a lateral or stop its growth checks it to a certain extent, which is very undesirable when the fruit is setting. Some Grape-growers recommend the temperature to be a little lower at the time of flowering. Our houses are kept about 5° higher, and the setting of the fruit is aided by merely shaking the bunches gently. No doubt the high winds have been of some service in distributing the pollen. We have had continued gales from the west for the last ten days.

When all the fruit was set the borders had a good watering with manure water. The inside borders of the late vineries have also had a good watering with manure water. The Vines are breaking freely, and the houses are now kept close.

The more experience we have with keeping late Grapes so much the more are we convinced of the importance of ripening them early. Late-ripened Grapes are not sufficiently firm in the flesh to keep well until March or April.

We intend to inarch some of the Vines in the late houses this season, and preparation is made for it. The most complete union is made by uniting green wood to green. We allow the shoots to grow about 4 feet, then take a slice of each about 8 inches in length, with a sharp knife cutting clean and to the centre of the growths, bring them together, and tie firmly with soft matting. The growth on the stock should be pinched-back to a leaf above the union, and the new Vine will make a fine bearing shoot the first season if it is allowed space to develop itself.

Those who grow Vines in greenhouses or conservatories labour under disadvantageous circumstances, not only when the Vines are starting, but all through the season. Before the Vines start in spring it is necessary to shade the house for Camellias and other flowering plants, and in the summer it is necessary to shade the house and air it more than the Vines like. If New Holland and Cape hardwood plants can be removed out of the house from the end of May Camellias and some other plants require the same treatment as Vines—namely, a close and warm temperature with syringing twice daily. If a supply of flowering plants has to be kept up in the greenhouse during summer it is much better not to grow Vines.

PLANT STOVE AND ORCHID HOUSES.

Some of our plants still require repotting, and they will be attended to as soon as possible. If plants are in a healthy state, and the pots pretty well filled with roots, a liberal shift may be given to them. Others may be unhealthy from the compost becoming sour; it will therefore be quite as necessary to repot them, removing the sour compost and repotting in smaller pots. Nearly all the stove plants are now growing freely, and a higher

temperature is necessary—not less than 65° at night with an increase of from 5° by 15° by day. If the weather is dull it is not well to try to maintain a high temperature from artificial heat, but in bright sunshine, even with a shading on, 80° may be reached; and if the house is closed between two and three in the afternoon with this temperature much less artificial heat will be required.

Ixoras are breaking freely, and require a plentiful supply of water at the roots and to be freely syringed. The climbing plants are now starting into growth. Our object is to keep them free from insect pests, especially mealy bug. If this pest is in the house it will find its way on to Dipladenias, Stephanotis, Cissus discolor, and Hoya carnosa. The young growths of the above twine tightly round the wires, but they ought not to be allowed to do this, as the plants cannot be loosened down without cutting all such growths off.

Achimenes and Gloxinias are much admired by some, but we had not sufficient accommodation for them and had to discontinue their culture. To grow them well they should be grown in a position near the glass, and Achimenes are the better of a little bottom heat. The pots containing the tubers should now be watered, and when growth has commenced they should be repotted. The plants do well in turfy loam and fibrous peat with a little sand and decayed manure added, draining the pots well. No plant will continue in health if the pots are not well drained and the drainage kept free from loose soil. It is necessary that superfluous water should find egress freely and at once.

All free-growing stove plants require plenty of water, but it must not be applied when the plants do not require it. There is a much closer connection between the vegetable and animal kingdoms than most people are aware of. If any members of either are gorged with food when it is not required they will not remain long in health. An animal will not drink unless it is thirsty (some human beings have not so much sense), and a pot plant will suffer if it is frequently watered before the soil is sufficiently exhausted of moisture. Another point of resemblance is in the fact that cleanliness and fresh air is quite as necessary for one as the other. One is often asked by the inexperienced, "How often must I water my plants?" Now this all depends on circumstances—whether the atmosphere of the house is dry or moist, and whether the pots are full of active roots. Every cultivator must learn from experience. If cuttings are not yet put in of the usual softwooded stove plants for flowering in autumn, this ought to be done at once.

Many of the Orchids have been repotted, and others have been placed in fresh baskets or on blocks. Some it was thought better not to shift out of their pots or baskets; these have been surfaced with fresh compost. This is a good time to shift the large genus of Dendrobium. This ought to be done as soon as there are signs of growth. We have in flower at present the very beautiful *D. litiflorum*. This is a more elegant plant than *D. nobile*. It very much resembles *D. nobile* in the flowers, but the growths are more slender. This is a very free-flowering species that ought to be grown in every collection. There is some difficulty in obtaining good Orchid peat and sphagnum in some districts. Our experience with many Orchids is, that if clean crocks are used as a potting material this is often better than using either peat or sphagnum for Vandas, *Aërides*, and *Seccobolabium*. We have seen plants of the above turned out of the pots, and the only live roots were those that had been formed above the compost, all that had run into it being found either dead or dying.—J. DOUGLAS.

HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

BRIGHTON (Spring Show). March 22nd and 23rd. Mr. G. Webley, Holm Wood, Westbury-upon-Trym, Hon. Sec.
GLASGOW. March 20th, May 10th, and September 12th and 13th. Mr. F. Glibb, Doughty, 167, Canning Street, Sec.
ROYAL CALLEDONIAN HORTICULTURAL SOCIETY. Shows April 5th, July 5th, and September 13th.
WESTMINSTER AQUARIUM. April 12th and 13th, May 10th and 11th, May 30th and 31st, July 5th and 6th.
